In the short discussion which followed, Mr. C. E. Kenneth enquired the reason why Japine and sepia papers persisted in showing a slight yellow tinge in the whites compared with the image papers. Another member asked if the lecturer did not consider the present price of platinotype papers to be excessive. Smith, in reply to both questions, said that a "natural colour" paper was utilised for the sepia and Japine platinotypes; it afforded a more harmonious base, and was preferred by the majority. The so-called "blue" paper was employed for the black image platinotypes. Comparing the two, the former would appear to be of a slight yellow tint. As to the price of the papers he most certainly did not think them dear; indeed, the reverse was the case, considering the high price of the metal itself, which had enormously risen in the last few years. At the instance of the vice-chairman, Mr. Terry, a hearty vote of thanks was accorded the lecturer.

## PORTRAITURE WITH THE MERCURY-VAPOUR LAMP.

The character of the light from the mercury-vapour lamp is different from what might be imagined, and without any diffusing medium the illumination is soft and even. A diffusing screen of butter muslin, *papier minéral*, or other translucent medium, however, makes the light still softer and more pleasant to the sitter. A point of advantage of the light, particularly in small studios, is that no extensive fittings are needed, wiring with a minimum capacity of three amperes, terminating in a small wall plug, being all that is required. In a studio of good size it might be advisable to have two or three of these wall plugs, so that the length of loose wire is not excessive. This simplicity of installation enables the photographer to remove the lamp during the summer months, and there is nothing unsightly remaining.

The lamp will commend itself for studio use on account of its cleanliness. Some forms of artificial light produce a good deal of smoke and dust, but with this apparatus there is nothing to give rise to either of these objectionable drawbacks. Neither are there any difficulties in the working of the mechanism which need alarm those who are unused to the handling of electrical appliances. The starting of the lamp is very simply managed, to cut off the current it is only necessary to withdraw a plug, and while the lamp is running it requires absolutely no attention. Being almost silent in running, and giving off little heat, it is free from those distractions alike to the sitter and the photographer, which so often conspire to injure the expression at the vital moment of exposure.

#### Lighting Precautions.

A few points with reference to the actual lighting of the sitter may be helpful to those who have already installed the lamp. If the tubes are placed too close to the sitter there will be a flattening of the modelling on the light side of the head, while at the same time a harsh effect will be produced. It is most probable that this mistake, coupled with the improper use of reflected light, will lead to most of the initial failures. Care must be taken that the light from the tubes illuminates the reflector adequately, or there

will be a deficiency of reflected light. It is sometimes forgotten that the reflector is not a source of light, and that obvious cannot reflect light which does not reach it. By keeping the reflector at some little distance from the sitter and using a large area of light, the reflector, not too near, sufficient shadow detail may be secured, that kind of modelling which is never obtained when the face is flooded with an excess of light. True, it is important to keep exposure within reasonable limits, and in some cases, with children or nervous sitters, it may be well sometimes to sacrifice a certain quality of modelling to this shortness of exposure; but in general a slightly longer exposure is a small price to pay for good modelling and effective light and shade in the features, but for the average sitters the difference between one and two seconds is almost immaterial. This is in the nature of a digression, applying, as it does, generally and not more particularly to the mercury lamp than to any other artificial light or daylight. But it is mentioned here because, using any movable form of light there is a tendency to get too near the sitter as possible, under the mistaken idea that the effect is the same and the exposure less. Where a large illuminating lamp is employed it is always more difficult to control the lighting, or, in other words, a greater movement of sitter and camera is necessary to produce any marked difference in the effect.

#### Mercury-Vapour plus Daylight.

It is interesting in this connection to recall the use made of mercury-vapour tubes by Mr. Pirie Macdonald, of New York, who, when the daylight is failing, starts his lamp tube by tube, the first light providing the soft and general illumination, while the second direct beam from the single tube gives a touch of force and brilliancy to the lighting of the head. When the lamp is being used for evening work, much the same effect may be secured by the use of a diaphragm head screen, a large circle of tracing linen with an opening in the centre which allows a beam of direct light to reach the head, the combination of diffused and direct light giving a perfect combination of softness and brilliancy.

the lamp will be found of value for making sittings where three or four different positions and lightings of a head are required. The work is usually better done for being done quickly, the sitter being worried by re-arrangements as little as possible, and the photographer's time being economised. The art of setting the head and shoulders so that the effect is good from more than one standpoint should be acquired, and then by slight movements of the camera the various negatives may be taken, the lighting being modified as required by moving the lamp a little.

#### The Cost of Running.

Two important points must be referred to—the cost of running the exposures necessary. The cost is remarkably low; the lamp when running continuously only taking about half a unit per hour. Supposing the current to cost 6d. a unit, we get at once a consumption of 3d. per hour. Of course, the time for a sitting depending on the class of work done and the number of plates used, the actual cost per sitter will vary, but assuming that three sitters are needed per hour the cost works out at a penny per sitter. If a number of incandescent glow-lamps are used to supply the red rays in which

the mercury-vapour light is deficient, the cost is somewhat increased, but supposing it to be doubled, a light charge of 2d. per sitter is almost negligible.

On account of the tendency to strong contrasts with all artificial lights, it is probable that the most rapid plates will be employed, especially as such may now be obtained at ordinary prices. With such plates, and using an aperture of  $f/6$ , the exposures for head and shoulder portraits will be found to work out at about  $1\frac{1}{2}$  to 2 seconds. The exposure naturally varies according to the character of background used, and the distance from lamp to sitter; but this time will be found a fair average.

In concluding these notes, the writer would say that they are based upon the use in his studio of the new mercury-vapour lamp of Schott and Genossen, Jena. No doubt the experience gained would be found to apply to any lamp of the mercury-vapour class. The writer would also like to be allowed to thank the British agent for the lamp, Mr. A. Iserthal, of Mortimer Street, W., for much friendly advice on the electrical side of the use of the lamp.

PROFESSIONAL.

## THE PICTORIAL WORK OF F. BENEDICT HERZOG.

The present exhibition of the Photographic Salon contains two examples of the photographic work of an American, Mr. F. Benedict Herzog, whose large picture, "A Tale of Isolde," was shown last year at Pall Mall. Our opinion of Mr. Benedict's photographs was expressed recently in the conclusion of the notice of the Photographic Salon, and we can add no higher praise of this extraordinarily clever photographer than what we have already said. We may, however, quote an account of Mr. Benedict's work which appears from the pen of Mr. Roland Rood in our New York contemporary, the "American Amateur Photographer," in accompaniment of some eight reproductions of the photographs, some of which have not, as far as we know, been seen in this country.

There has long been a complaint of the art critic that photographers so rarely evince originality that they copy the ideas of painters, and what originality they possess expends itself in improving their mechanics of production—in other words, that their highest claim to the title of artist lies in being technicians. In this view I heartily concur. It is therefore with pleasure that I offer the following to the consideration of the reader, for in Mr. Herzog we find a man who has passed beyond the mere student stage where desired exposure and development, correct values and clever printing and the imitation of the ideas of others seems everything; he has entered that broader field of thought where the æsthetic qualities assume their commanding position. As this type of man is not often found using the camera, it may be of interest to the reader to be initiated a little into these higher "secrets." To do this it will first be necessary to make some explanations regarding impressionism.

Impressionism can be defined as the fixing on canvas or paper of the first momentary impressions we receive when we suddenly look at any natural scene or object. Now in the first instant we do not properly think, but we distinctly feel, and the object of the impressionist is to convey that momentary feeling. This method of painting has one decided advantage over all others. The element of thought not being in the picture, the spectator is only made to feel; and as feelings unmingled with thought (which is a mixture of questions, contradictory assertions and judgments) are much stronger than feelings to which thought has been added, such a picture will produce a much stronger impression than one which may really have more thought; and as people are prone to judge rather from the strength of their feelings than from their logical conclusions, will receive more credit than it deserves. Impressionism, in its strictest sense, of necessity precludes any composition which rises above the simplest arrangement, and it is that which is so attractive to the youthful student, for he feels that with this kind of art he, too, may have a chance.

Successful as the French impressionists have been in fixing their impressions on canvas, I doubt if they have (minus the question of colour) done it any better than the photographers. The photographic impressionist is the finished snap-shooter. At the outset of his career he is perfectly thoughtless and snaps at anything and everything which produces an impression on him. It is only necessary for him to become conscious that he is feeling a sensation to be impelled to press the button. His results are bad, not because his mind is not

of the proper quality, but because owing to lack of optical knowledge he chooses to photograph such effects of light and perspective as are not within the grasp of the camera, and also because he knows nothing of values, exposure, developing, printing and pictorial arrangement. But if he persists and acquires technical power, and if his mind is sufficiently open to impressions, he evolves into the full-fledged impressionist and produces that class of work which may be classed as topographical or historical records, as for example, pictures of foreign landscapes and street life, of parades and public functions, of races and fires and accidents, etc., all of which are well worth presenting, but are the most pleasing when represented in a simple impressionistic way because we want to know—when we see a picture of this kind—exactly what the thing looked like, and not what its pictorial possibilities may have been.

Beautiful and interesting, however, as are these photographic impressions, the reader, of course, understands that they cannot be looked upon as the final goal of pictorial photography; they are but the first step on the road to ripe art. The second step is the addition of thought to the impression. I must here digress again to make some psychological distinctions which I have touched on before, but wish now to bring fresh to the mind of the reader, as they are very essential to the explanation of Herzog's work.

When I look out of my window I perceive (in psychological language) spaces of blue, streaks of gray and brown, patches of yellow and green, which in themselves are quite meaningless. But as I look I add to it thought gained from previous experience and apperceive these colour blotches to be a forest under a blue sky. As I continue gazing I add more and more previous perceptions. I think of the forests, and how I wandered through them, and how strong and large the trees seemed, and of what strange adventures I had there; and little by little, without being at all conscious of it, I have added so many of my past feelings to that forest that it no longer seems the same. And if in that half dreamy, half thoughtful state of mind I were to paint it, I would paint, work conscientiously as I liked, something quite different from the picture traced on the retina of my eye. I would not paint the forest, but my apperception of it.

Now in these two states of mind lies the main distinction between the impressionistic and the idealistic schools of painting. The impressionist perceives and the idealist apperceives; and the impressionist in only perceiving makes us only perceive (and very frequently not that, for perceptions without previous thought added to them are

often quite meaningless); but the idealist in apperceiving makes us apperceive and throws us into a reflective state of mind.

Let us see how the above principles can be applied to the practice of photography. The photographer unfortunately cannot work as does the painter; no matter what are the state of his feelings the lens pays no attention to them but transcribes a simple perception on the sensitised plate. How can the photographer change the mind of the lens and make it do as he wishes? The painter is not confronted with this problem; he makes such alterations as he deems necessary at will, or, as is usually the case, when under the influence of a strong apperception, he alters unconsciously and draws his objects in such a way as to embody many different feelings. He unconsciously eliminates, adds and exaggerates. But the photographer must always proceed knowingly. How, then, can the photographer transcribe his apperception to his sensitised plate? The simplest way that I can answer these questions, and at the same time come to the main point of this article, is to describe the idealist method of work.

Unlike the impressionist, he starts with a preconceived idea. He is possessed with a feeling more or less strong of what he wants to do. And this feeling which formulates itself in his mind in the shape of a composition, vague or distinct, depending upon the force of his imagination, has come there he hardly knows how—possibly from a picture by another artist; or from suggestions in one of his own; or from something he has read; or from something he has seen in nature—but originate this feeling as it may, it possesses and worries him until he has expressed it, until he has gotten it out of himself and given birth to it in the shape of a finished picture. And this is distinctly Herzog's attitude toward art and nature. When the idea has taken hold of him he sets to work like any other idealist with the requisite knowledge and makes studies upon studies; studies of detail; studies for line and light and shade, and studies for the whole composition. Only these studies, or sketches we may call them, are made with the camera. And when he has collected a sufficient number and gained a clearer idea of the nature of the apperception he is trying to express, and of how to express it, he poses his models into more complicated groups, preserving what he likes and eliminating the rest, and so on until at last the whole, to the smallest detail, is expressive of his original idea. Generally, however, where the conditions render it impracticable to produce the best results by the process of photographing the entire motif on one plate, he takes various parts of different plates and makes a composite from them. In cases these compositions may consist of as few as two figures, in other cases of many figures.

It is not astonishing that with a conception of art and mode of procedure so different from that of most other photographers his productions should also be different.

When eighteen months ago I was reviewing an exhibition at the Camera Club, the dozen Herzogs which he had hung there upon the occasion of his election as president, impressed me with their singularity. They were not matured in the sense they are now, and I hesitated to criticise; for all that I clearly recognised their potentiality and wrote as follows: "When I look at a Herzog I always feel that his work is totally different from that of any other photographer. I have never yet grasped its meaning, so will refrain from criticism, except to say that in a Herzog you can feel the reverberations of the thoughts of the old masters (after they have passed through his intellect and become imbued with his personality)—Titian, Veronese, Rembrandt, and so forth—Herzog is the only photographer I ever heard of who has attempted to combine the merits of Michelangelo and Franz Hals." The short time, however, that has elapsed since then has been sufficient to show me that I was right. The old master

feeling has become stronger, but more individual and expressive his own personality; his control over his models is greater; incongruous combinations somewhat less frequent, and I feel to-day entitled to assert that in the combination of the sense of beauty, and line, and classical, and romantic composition, excelled by no other photographer in America. It is also safe to say that in the handling of drapery he can hold his own with the painters. This is enough said when I add that he is but an infancy—photographically. It may be interesting to note that he also paints, and it is not impossible that his understanding of painting may have helped in giving him his broad view of art. That is right in my deduction that his pictures are apperceptive productions and not merely perceptive impressions is, to an extent, proved by the fact that everyone who sees them instinctively criticises them as if they were black and white paintings and not black and white photographs. In this respect his work is like Mrs. Barton's. In fact, it is work like theirs and the Viennese workers, and Clara H. White's and a few of the other secessionists that make me believe the lens may possibly some day be used not merely as a means of art expression—that is an old story—but as a means of Fine Art expression. By this I mean that it has been accepted by all intelligent critics twenty years and more ago that photographs could be artistic, tasteful, beautiful, etc., and so, too, may an old chair, but this in no sense implies that such a beautiful chair photograph can at all be ranked as a Fine Art production; it is infinitely more than that to validate such a claim. The point often advanced by photo-enthusiasts that because a photograph can be recognised as being made by so and so, and because it is possible of his personality it must also in consequence be a work of Fine Art is probably the most fallacious cant that ever was uttered. I can recognise a Columbia bicycle from an English Humber at a glance, and that because they both bear the impress of the personality of their creators; I can recognise the paintings of Y as far as I can tell, because they are so strongly expressive of his personality, but it so happens that the personality of the creators of the Columbia and Humber bicycles was scientific; and the personality of Y, although strong, is essentially inartistic, and very naturally, therefore, most of the productions can possibly fall, not merely within the realm of the Fine Arts, but even of the arts "ordinaire." To be personally expressive does not mean to be artistic; hoodlums are also personally expressive and capable of expressing their idiosyncracies, clumsiness and dilettantisms; and this they do just as much in the way they throw a suit of clothes or putt a golf ball as in the way they handle a brush.

There is another feature in Herzog's work which should be encouraging to all workers with the lens. His prints grow on you; you often see them, and this is diametrically opposed to the photographs usually do as every observant critic has remarked. It indicates clearly to me that the lens in the right hands is as capable of registering an apperception as a perception, a thoughtful revelation of nature as a superficial glance.

On reading what I have written I fear that because I have criticised Herzog with Mrs. Barton and White and the Viennese workers it may be understood that I mean he is as capable an artist as they. This is far from my meaning. I have merely classed him with them because they all have the same order of mind; Herzog's work is yet exceedingly incomplete, but as such possibly better illustrates of art principles, for in thoroughly expressed work like that of Mrs. Barton, or White, or Mrs. Käsebiel, or Day, the machinery of construction is not so easily seen and understood. Still, Herzog passed his first student days and entered the field of broad apperceptive work, and for that deserves consideration.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—Mr. A. H. Downey has been appointed hon. secretary in succession to Mr. H. C. Beckett. Communications for the society should now be addressed to Mr. Downey, at The Laurels, Slaitwaite Road, Lewisham, S.E.

**VOIGTLANDER LENSES** have just obtained another award. At this year's Photographic Exhibition, held under the auspices of the German Photographic Union, the lenses of the celebrated Brunswick firm have again been awarded the first prize gold medal for perfection in material and workmanship.

**WE** hear that Messrs. Holmes Bros. have removed to 41, Oxford Street, Manchester, and that this old and well-known firm intend to devote their attention to the supply of requisites used by the professional photographer.

**MR. HARRY WADE**, of 29, Blackfriars Street, Manchester, intimates to us that he will be pleased to arrange with the secretaries of societies in the Midlands and the North to give his lecture "Recent Advancements of Photography," on behalf of Messrs. Wellington and Ward.

## Exhibitions.

### BRISTOL CAMERA CLUB.

The exhibition opened on Saturday last at the splendid suite of rooms of the Bristol Fine Arts Academy was inaugurated by the Bristol Photographic Club. Being quite a young society, their enterprise in deciding to hold an exhibition on so large a scale is most praiseworthy, and shows an energy and enthusiasm among the members that other societies throughout the country might well emulate. All have worked hard to make it a success, as it most assuredly is artistically, and, it is to be hoped, financially.

For the hanging, Mr. Percy Lewis has been largely responsible, and he shows five of his well-known Venetian scenes in the invitation section. "Venice, the City of Dreams," a characteristically delicate bromide print, full of "atmosphere." "A Misty Morning, Venice," is also a bromide, while the remaining three are in carbon, and well known. Mr. Abel Lewis (Mr. Percy Lewis's father) shows three fine carbons, the one entitled "Portrait," the head of a boy, being specially noteworthy.

The works hung in the principal saloon are exclusively devoted to the competitive sections, and it may at once be said that the standard of excellence shown makes the exhibition compare favourably with the very best of provincial shows. A detailed description of the accepted works would be impossible in the space at our disposal, but special mention may be made of "Mouth Drinks Adventure, Poverty Forgot," by H. Holt, a small picture in dark green, of a young Dutch girl reading. Beautiful in composition, this work suffers only from being too small. "All the Sea of Harvest Rolling Round," by H. Youel Summons, a delightful landscape of lovely quality. "A Corner of the Cloister," by W. A. Clarke. "Hope Deferred," by J. S. Guthrie, a well-posed and well-lit head of a young girl. "At Piéne de Cadore," by R. A. and W. A. Duncan, an excellent Swiss landscape, and good in composition. "The Harbour," by H. Bedell, with its large white vessel and shimmering water. "Winter," by H. H. Blades. Though this has received the highest award in its class, the composition is not quite good, being too one-sided. "Winter's Eve," by J. E. Atham. "Snowdon Veiled in Grey Vapour," by Graystone Bird. "A Relic of the Past," by D. G. Kimber. "The Picture Book," by George Easonsmith. "A Venetian Pearl," by Arthur Marshall; a fine piece of work, which, however, suffers from a want of contrast, though so delicate, some darker point of interest is necessary to relieve the feeling of general flatness. The same remark applies to this worker's "Venice." "The Golden Light of the Early Dawn," by F. J. Phillips.

Passing into the next room we find ourselves among the works of the Champion Class, the principal award being given to "October," by F. Judge, a print of a curious and rather bilious colour by daylight; still, it is a really fine work, and quite upholds the judges' opinion of it. "Gloria," a fine cloud effect, by Graystone Bird. "Aisles of Pleasant Shade," by C. R. Armstrong, a South African exhibitor. "Japanese Anemones," by Dan Dunlop; an exceedingly beautiful and artistic flower study. On screens in the same room is a large collection of prints by R. Dührkoop, some of which are very beautiful, but some very mediocre work, from an artistic point of view, is also shown. Another room is devoted to the loan collection, but as much of the work shown has been seen and reviewed over and over again, it will suffice to mention that the following artists have contributed:—W. Clayden, F. H. Evans, W. C. Crooke, Chas. Job, A. L. Coburn, Abel Lewis, Percy Lewis, F. J. Mortimer, W. A. Duncan, Alex. Keighley, Horsley Hinton, W. Thomas, W. Bennington, and a small collection by the Marshalls Club. The lantern slide exhibits are perhaps not quite up to the level of the prints; still, some excellent work is shown, notably those by F. Little.

Stalls for the exhibition of apparatus, etc., have been taken by a number of well-known firms.

The judges were Messrs. Reginald Craigie, F. H. Evans, and Frank M. Sutcliffe.

The following is the list of awards in the open classes:—  
Champion Class.—F. Judge, "October" subject, silver gilt

plaque; S. G. Kimber, "A November Morning," silver plaque; S. G. Kimber, "A Sunlit Clerestory," bronze plaque; F. Little, "End of the Day, Bristol Harbour," bronze plaque.

Landscape, Seascape, and River Scenery.—W. H. Blades, "Winter," silver; B. H. Bedell, "In Harbour," bronze; F. J. Phillips, "In Golden Light of Early Dawn," bronze; F. J. Tucker, "Whitby," bronze.

Portraiture and Figure Studies.—D. Dunlop, "A Fair Norwegian," silver; H. Holt, "Grim and Stern," bronze; A. Elliott, decorative panel, bronze.

Architecture, Interior and Exterior.—A. Marshall, "A Venetian Pearl," silver; S. G. Kimber, "A Relic of the Past," bronze.

Fruit, Flowers, and Still Life.—D. Dunlop, "Japanese Anemones," silver; A. W. Walburn, "Wild Apples," bronze; H. R. Harford, "Gooseberries," certificate.

Any Other Subject.—F. Marsh, "Nightwork in a Paper Mill," silver; A. Leader, "The Speech of the Trees," certificate.

Lantern Slides.—F. Logan, Leicester, "Street Scene," silver; W. Marshall, Grangemouth, "Evening," bronze.

General, any subject (open to residents within 25 miles' radius).—F. Little, "The End of the Day," silver; H. O. Isaac, "The Evening Train," silver; D. L. Fullerton, "With Ships the Sea was Sprinkled," bronze; A. E. Burnett, "Chantry, Wells," bronze; H. C. Leat, "Mowwinston Church, Cornwall," certificate.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received from September 24 to September 29:—

**FOCAL-PLANE SHUTTERS.**—No. 21,132. Improvements in self-capping focal-plane shutters. William Watson, 45, Chestnut Walk, Walthamstow, London, E.

**FILMS.**—No. 21,189. Improvements in photographic films. John Edward Thornton, Altrincham, Cheshire.

**MOUNTING PHOTOGRAPHS.**—No. 21,229. Improvements in mounting photographs. Peter Peters, trading as the Pictorial Photo. Publishing Co., 8, Quality Court, Chancery Lane, London, E.C.

**ENLARGING APPARATUS.**—No. 21,312. Improved repeating back for photographic enlargers. Albert Edward Terry, and Houghtons Ltd., 88, High Holborn, London, W.C.

**STEREOSCOPIC APPARATUS.**—No. 21,462. Improvements in stereoscopic telemeters. Christian von Hofe, Jena, Germany.

**TONING SILVER PICTURES.**—No. 21,584. Improved process for converting silver pictures into pictures in higher oxides of manganese and for toning silver pictures. Neue Photographische Aktien Gesellschaft, Birkbeck Bank Chambers, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**COLOURED PRINTS.**—No. 22,580, 1905. The invention consists in the production of coloured tones on photographic prints by a series of chemical baths, which tones can be altered more or less by heat. The process is thus described by the inventor for P.O.P. though it is not limited to prints on this paper:—

The P.O.P. is printed to about half the usual depth, and is immersed in a bath of:—

No. 1. Pyrogallie acid..... 1 grain.

Water ..... 3 ozs.

and developed until the required depth of shadow is obtained, after which it is placed in a fixing bath of

No. 2. Hyposulphite of soda..... 2 ozs.

Water ..... 18 ozs.

for about ten minutes, until the image is fixed. It is then washed in water for one hour.

The print is now ready for the colouring process, which is best taken in the following order.

The print is first immersed in a bath of the following:—

- No. 3. Saturated solution sulphocyanide of ammonia..... 15 drops.  
Saturated solution acetate of lead 1 to 2 drops.  
Saturated solution bichromate of potassium ..... 2 drops.  
Chloride of gold solution..... 1 drachm.  
Water ..... 3 ozs.

It is allowed to remain in this bath, until the image assumes blue shadows with pink half tones, and at this stage, if the print is taken out and dried, the colours will be found to be susceptible to change on the application of heat. If desired, however, the pink half tones may be further changed to heliotrope by placing the print in a bath of

- No. 4. Pyrogallie acid..... 1 grain.  
Water ..... 3 ozs.

The high-lights of the picture may now be cleared from the possible staining action of the previous bath, by immersing the print, after washing, in a bath of

- No. 5. Saturated solution ferricyanide of potassium ..... 4 drops.  
Water ..... 3 ozs.

It is then washed and dried.

The colours of the print are now sensitive to heat, which may be applied in any suitable manner, say by means of a hot iron or similar instrument held close over the sensitised surface of the print. The blue colours may, in this manner, be changed to purple, red, brown or crimson, according to the intensity of the heat applied. The heliotrope shades, produced by the No. 4 bath, may be changed in a similar manner by heat to varying shades of red.

Yellow tints may now be imparted to the print by inserting it for about two minutes in a bath of

- No. 6. Saturated solution of any soluble lead salt ..... 1 drachm.  
Water ..... 4 ozs.

after which it is passed through the following

- No. 7. Saturated solution bichromate of potassium ..... 10 drops.  
Water ..... 4 ozs.

The parts already acted upon by heat are not changed to a yellow colour by these baths, but a deposit is formed thereon which must be afterwards washed off. When the print is dry, the yellow shadows may be changed by means of heat to a deeper yellow or orange colour.

If the acetate of lead is omitted from the No. 3 bath, and applied locally on the print, and the bichromate of potassium made stronger in the No. 3 bath, the toned print, after passing through the wall, will have blue shadows with local yellow colourings.

The blue colourings on the print obtained in the way described may be intensified by a bath of

- No. 8. Saturated solution ferricyanide of potassium ..... 4 drops.  
Saturated solution ferricyanide of iron ..... 4 drops.  
Water ..... 4 ozs.

The intensified blues so produced are capable of being changed to green by the application of heat as before described.

Any parts of the photograph, in addition to those acted upon by heat, that may not be required to take a yellow colouring when passing through the baths Nos. 6 and 7 mentioned above, may be treated with a solution of sulphite of soda after the print has been passed through the No. 6 and before it is immersed in the No. 7 bath. Edward John Browne, 2, Chiswick Lane, Edge Lane, Liverpool.

**DARK SLIDES.**—No. 18,413, 1905. The invention consists broadly of a plate or firm carrier carrying the plate or film and provided with a retaining strip over which carrier a light-tight casing of cardboard, also serving as exposing slide, is passed in such a manner as to be held under the sides of the retaining strip which

are bent up on both sides, thereby providing a reliable light-tight slide. The casing serving also as exposing slide is provided with a metal rim to increase its stability, this edge likewise serving for uniting the two slide surfaces. The exposure takes place in a rear, light-tight adapter in which the retaining strip the plate or film carrier is suitably supported so as to prevent from being withdrawn inopportunely. Neue Photographische Gesellschaft, 27, Siemenstrasse, Berlin-Steglitz.

**"COOKE" LENSES.**—No. 24,391, 1905. The claim is for a quadruplet lens consisting of two exterior simple bi-convex positive lenses enclosing between them two simple bi-concave negative lenses the refractive indices being so arranged that while the glass of one negative lens has a substantially lower refractive index than the glass used for the positive lens adjacent to it, the glass of the other negative lens has a substantially higher refractive index than the glass used for the positive lens adjacent to it, while the sum of the powers of the two negative lenses is about 93 per cent. of the sum of the powers of the two positive lenses, a condition necessary to the attainment of a flat image substantially free from astigmatism.

In the combination made on these lines:—

1. The Petzval condition is to be approximately fulfilled.
2. The positive lens to have the highest refractive index in one half of the lens, and the negative lens to have the highest refractive index in the other half of the lens.
3. All lenses to be double convex or double concave.
4. It is desirable, but not essential, that three lenses at the very least shall have high refractive indices.

Owing to the fact that the four lenses are all of different glass the designing of the combination is found a much more difficult thing than the designing of a symmetrical combination in which one-half is simply a reversed repetition of the other, but the following combination yields a photographic lens of an aperture equal to F. 6.7, and covering a plate whose longer side is equal to the equivalent focal length.

The Figure 1 of the Provisional Specification serves perfectly well as an illustration of the finished lens, the radii of curvature given below referring respectively to the surfaces as counted

from left to right, the four lenses also being counted left to right as  $L_1$ ,  $L_2$ ,  $L_3$  and  $L_4$ ; also the three axial air-spaces  $A_1$ ,  $A_2$  and  $A_3$  being enumerated from left to right. The equivalent focal length is supposed to be unity while the curves, thicknesses, air-spaces and diameters for any desired lens of equivalent focal length =  $N$  may be had by multiplying the figures below by  $N$ .

Glasses.

Refractive Indices for Dray.

- $L_1 \mu_D = 1.6058$   
 $L_2 \mu_D = 1.6244$   
 $L_3 \mu_D = 1.5420$   
 $L_4 \mu_D = 1.5902$

Reciprocals of Dispersive Powers for spectrum interval C to F.

- $\gamma = 43.8$   
 $\gamma = 39.7$   
 $\gamma = 46.8$   
 $\gamma = 61.2$

Back focal length measured from vertex of 8th surface = .786

Aperture of stop for  $\frac{F}{8}$  = .1177

Curves, &c.

$L_1$  {  $r_1 = +.2139$  Axial thickness. = .0246  
       {  $r_2 = +.7070$  Finished diameter. = .1600

Air Space  $A_1 = .0107$

$L_2$  {  $r_3 = -.3208$  Axial thickness. = .0032  
       {  $r_4 = -.3278$  Finished diameter. = .1500

Air Space  $A_2 = \text{about } .0267$

$L_3$  {  $r_5 = -.5882$  Axial thickness. = .0032  
       {  $r_6 = -.3417$  Finished diameter = .1500

Air Space  $A_3 = .0086$

$L_4$  {  $r_7 = +.5882$  Axial thickness. = .0246  
       {  $r_8 = +.2166$  Finished diameter = .1600

Adjustments.

As the glasses vary somewhat in different meltings, rendering slight departures from the above figures often desirable, the effect of varying some of the above data should be known.

In the first place each half of the lens should be fixed together in a self-contained mount and may be tried telescopically on a distant point of light with the negative or dispersive lens facing the latter, and using an eye-piece free from spherical aberration. Then the separation between the two lenses should be adjusted until the image of the distant point of light is about free from spherical aberration. Next, after screwing both halves into the mount the lens should be tried as a whole upon the same point of light in the same manner, but with  $L_1$  facing the latter. Then the separation between the two halves should be adjusted until the performance of the lens upon pencils passing obliquely through it, say at an angle of 20 degs., show a slight amount of over-corrected astigmatism, a condition which accompanies a flat image. Also if the spherical aberration of the axial image is not quite satisfactory, the two positive lenses  $L_1$  and  $L_4$  may be either screwed inwards towards the centre stop or outwards, the former tending to over-corrected and the latter to under-corrected spherical aberration. Then the lens may be tried in the camera with  $L_1$  outwards, and the two halves further adjusted until the image is got satisfactorily flat over a length of plate at least equal to the equivalent focal length. Screwing the halves further apart tends to an over-corrected image convex towards the lens, and screwing them nearer together to an under-corrected image concave towards the lens.

Screwing both  $L_1$  and  $L_4$  outwards towards the distant object while keeping the axial spherical aberration constant, tends to produce outward coma in the oblique images, and screwing them both inwards towards the screen tends to produce inward coma. Each half of the lens may be used by itself with the negative lens towards the distant object, but as each half is not in itself either axially or obliquely achromatic, and also yields a lot of outward coma at the foci of oblique pencils, therefore it is necessary to use a small stop in order to obtain anything like good definition. The equivalent focal length of the front half ( $L_2 + L_3$ ) is about 2.5, and that of the back half ( $L_3 + L_4$ ) about 1.6. Harold Dennis Taylor, Stancliffe, Mount Villas, York.

**TRIPDS.**—No. 20,931, 1905. Ball-shaped projections, securely held by suitable means, are placed on the underside of the tripod head. These projections are placed under head, and the legs of the stand, links constructed with recesses of concave form at their upper ends so as to enable them to tightly clasp the ball-shaped projections. The bottom ends of the links are secured to the legs of the stand by bolts passing through the links and upper ends of the legs of the stand, and nuts, and the links are tightened so that the concave recesses in the upper ends of the links clasp the ball-shaped projections on the underside of the

tripod head, by means of a bolt or bolts passing through the links, and provided with wing or other nuts. William Butler, 20, Crosby Road, Birkdale, Southport.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—

**COLOUR PHOTOGRAPHY.**—No. 20,834. Manufacture of composite screens and plates for heliochromic processes. Berthon and Gams.

## New Apparatus, &c.

The "Reynaud" Quick Bromide Printer (Incandescent Gas Pattern), sold by Marion and Co., 22-23, Soho Square, London, W.

The new form of the printer is identical in its essential details with the first model (for electric light), noticed in our pages some months ago. In the gas pattern fitting, the switch on and off of the light is made by the very simple lever movement visible in the

figure. The average exposure for bromide cards is about one second, the price of the printer in this incandescent gas form being 40s., with three masks and pressure boards, in five sizes, from postcard to half-plate, burner, chimney, and mantle.

Since the appearance of our review, a month or two ago, an addition to the Welborne-Piper clock has been made, which distinctly enhances its practical utility. With the extra attachment the clock can (1) terminate a prolonged time exposure in the absence of the operator; (2) give an instantaneous exposure at any pre-arranged time, also in the absence of the operator. This addition can be supplied to any existing clocks at a cost of 12s., or the clock is supplied complete with the attachment for the price of £23 2s. Messrs. W. Butcher and Sons, the agents for the clock, will adapt existing instruments.

**PARAFFIN Incandescent Light.**—A new firm which should be able to do business with photographers in country places is the Invertrol Gas Light Company, Burton-on-Trent, the proprietors of a system of using ordinary paraffin for incandescent (mantle) burners of the inverted type. The company have a series of fittings for sale, particulars of which and of the cost of the light for household and business purposes are obtainable in a booklet just issued.

## New Materials.

Filter-Yellow-K Screens. Made by Wratten and Wainwright, Ltd., Croydon.

The commercial introduction of yellow screens prepared with the new dye filter-yellow-K, the ultra-violet absorptive powers of which are recorded by Dr. Novak in our issue for August '14, and by Messrs. Mees and Wratten in that of September 28, will place in the hands of the operator, both for pictorial and scientific work, a much more useful screen than we have hitherto been able to obtain.

Messrs. Wratten and Wainwright prepare these filters in three series, K I., K II., and K III., the first being suitable for landscape and hand camera work; the second gives full correction, but passing a slight preponderance of blue-green, that particular colour which is so difficult to reproduce correctly, whether in the form of foliage or pigment; the third is specially recommended for picture copying. The increase of exposures with Messrs. Wratten's plates is shown in the following table:—

Used with the	Allochrome	Verichrome	Pinachrome	Pinacyanol	Panchromatic.
Series K I.	... 3	... 1½	... 1½	... 1½	... 1½
Series K II.	... 8	... 5	... 5	... 5	... 3
Series K III.	... —	... 7	... 7	... 7	... 5

Testing these filters with the panchromatic plate on a colour chart, we find the action to be extremely satisfactory, and series K III. gives a perfect rendering of the luminosities of the colours, though probably in many cases series K II. will be preferred, because there is a little more colour contrast—that is to say, with the former an emerald green and vermilion of equal luminosity were rendered of equal tone value, whilst with the latter series there was a distinct difference between the red and the green. The great advantage of the improved rendering with such short exposures is very marked, and to obtain the same correction as was given with No. 1 we had to give four times the exposure with a special tartrazine filter.

The filters may be obtained in gelatine strip form at 4d. per square inch, or as cemented filters in 1½ inch circles, or squares at 4s. 3d., 2 inch at 5s. 6d., 3 inch at 9s. 3d., etc.

Mr. H. W. Green, Crown Photo Manufactory, Rotherham, sends us several neat examples of Christmas mounts issued by him in large variety at moderate prices. His six-page list prices and illustrates the cards, which bear appropriate mottoes.

THE Vanguard Manufacturing Company, Maidenhead, send us a sample of their sepia toner for bromides and gaslight prints, which they have now issued according to a new formula, insuring much more rapid action. We find the bleaching solution to act very quickly, inasmuch that the whole process is complete in little more than five minutes, including a minute or two's wash before the darkening bath is applied.

### CATALOGUES AND TRADE NOTICES.

In sending his current price list of enlargements, finished in black and white or colour, Mr. Robert J. Westley (13, Amner Road, Battersea, London, S.W.), submits to us a selection of his work, without which any quotation of his prices is meaningless. With the enlarged portraits before us, however, we can commend Mr. Westley's work, and recommend application for his price list. He makes a specialty of worked-up enlargements.

MESSRS. A. W. GAMAGE, LTD., High Holborn, notify us of their autumn sale of cameras and photographic sundries. A list will be sent on application.

The Westminster Photographic Exchange, 119, Victoria Street, Westminster, S.W., have issued a more than usually full list of photographic goods. Its 220 pages includes a great variety of apparatus, for which the firm will accept old goods as part

payment. A separate list of such second-hand goods also reaches us, and contains we observe, a number of bargains.

A SPECIAL list of enlarging requisites has just been issued the "Tella" Camera Company, 110, Shaftesbury Avenue, London W., the 36 pages serving to describe a variety of cameras and illuminants.

Lantern apparatus in great variety is described in a new issued by Messrs. Houghtons, Limited, and obtainable from them at 88 and 89, High Holborn, London, W.C.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday, the 4th, the association held their annual supper at the Hotel Boulogne, Gerrard Street, W. Amongst the members and visitors present were Messrs. F. A. Bridge, H. Stuart, J. Burgess, T. Grant, T. E. Freshwater, A. Haddon, E. R. Human, J. L. Tebb, H. R. Rapson, and others. Mr. A. L. Henderson presided. The toast of "The King," proposed by the Chairman, was received with musical honours. Mr. Freshwater proposed "The L. and P. and Mr. Rapson replied, urging members to attend all meetings. The toast of "The Visitors" was given by Mr. Ernest Human, coupled with it the name of Mr. Stuart, the President of the North Middlesex Society. "The Press" was proposed from the chair and "The Chairman" by Mr. Bridge, who said that he had been a friend of Mr. Henderson for 35 years. Mr. Henderson suitably replied and gave a short account of the birth of the Association of which he is the father and founder. Mr. T. K. Grant gave a statement of the evil times Mr. Sandell, of plate and film fame, had fallen upon, saying that it was exceedingly doubtful whether he would ever leave his bed, where he had lain for the last three months, and in an almost destitute condition. The sum of £5 2s. was subscribed for the room, and Mr. Grant said he did not know how to thank the company on Mr. Sandell's behalf. His feelings were too deep for mere words.

SOUTHAMPTON CAMERA CLUB.—On the 8th inst. the members of the above met for a slide criticism meeting. Two slides were projected on the screen, one the work of Rev. H. W. Dick,

other by the hon. sec., Mr. S. G. Kimber, and the members present were invited to make criticism thereon. Fourteen papers were handed in and a vote taken as to their merit, the criticisms of Messrs. W. R. Kay and A. E. Henley being adjudged equal in merit. The evening proved to be a most profitable and interesting one, and further efforts in this direction are projected.

## Commercial & Legal Intelligence.

**The Ownership of a Negative.**—Charles F. Hands, a photographer, of Clapham Road, was summoned last week for detaining four negatives of the South African football team, the complainant being Thomas Hanscomb, who alleged that the negatives were his property. The complainant, who is the manager of the Manchester Hotel, Aldersgate Street, explained that he obtained permission to take a photograph of the South African football team, on the strict understanding that it was not to be published in any newspaper, and was only to be used for charitable purposes. Two of the negatives were taken by himself and two by the defendant, but all the negatives were taken on his plates and by his camera. The defendant asked to be allowed to take away two of the plates to develop them. Subsequently the defendant told him that these plates had been spoilt, and upon being shown the other two said they wanted nothing. He allowed the defendant to have them for that purpose, and the defendant now refused to return them. He had been offered £10 for the two negatives. The defendant declared that three of the negatives were taken by himself, but the complainant denied that statement. Addressing the magistrate, the defendant asserted that it was arranged that the complainant and himself should make the group between them, the distinct understanding being that he was to have the negatives. Mr. Curtis-Bennett ordered the defendant to deliver the two negatives to the complainant forthwith, to pay £10, their value, together with 21s. costs.

**FLASHLIGHT Photograph.**—In the Clerkenwell County Court, last week, Messrs. Houghtons, Ltd., sued Bernard Cooper, Ltd., 31, York Place, Baker Street, for £12 10s. in respect of taking a flashlight photograph, including hire of camera and the operator's time. Frank Marshall, manager of plaintiff's photographic department, said that in accordance with an order received they sent an operator to the Mulhorn Restaurant to take a flashlight photograph of a dinner party. The work was done, but Mr. Cooper declined to pay. Mr. Carpenter (for defendant), producing a copy of the photograph, asked how the several white lines across it were accounted for. Witness: It appears to me that they have been what is called "faked." But I would like to see the negative, not a proof. From the conversation which the operator had with Mr. Cooper I took it that the negative was satisfactory. John Francis Chaplin, the operator who took the photograph, said he developed it in Mr. Cooper's dark room. As to the white lines he could only account for them by the unsatisfactory condition of Mr. Cooper's dishes and the sink. It might have been that some chemicals had fallen upon the negative. Replying to Mr. Carpenter, witness said it was impossible to get all the guests in the photograph owing to the angle at which he had to take it. Mr. Carpenter: But it is a usual thing for all the guests to be included in a photograph? Witness: Yes, but this was a Scotchmen's dinner, and the tables had been arranged to allow a space for them to march up and down. (Laughter.) The corner of the first table was three feet away, and the extreme distance was 150 feet. The lens on the camera will only take a certain amount. I said before taking the photograph that it would be impossible to get them all in. Don't you think these lines might be due to some defect in your lens?—No. It is out of the question altogether. For the defence Mr. Bernard Cooper said he thought the lines might have been caused by the electric light getting into the lens. He complained that the majority of the photograph was out of focus. The judge (examining the proof) looks as if some of the guests have moved. Witness added in his opinion, as the tables were arranged, it was possible to take a full photograph in the same way as it was possible to take a photograph of a whole room. He thought it would have been better if a number of flashlights had been placed round the room. As

the proof was not satisfactory, he told the operator that he himself had better go round to the guests and see if he could get any orders for the photograph. The operator declined to go, so he (witness) afterwards sent someone round. The Judge said he could not say that the photograph was a good one, but the cause of the defect appeared to be somewhat doubtful. It appeared to him that the lines of light were too regular to be caused by chemicals, and he should prefer to think that they were caused by light getting in somehow. Mr. Cooper, however, sent a man round to solicit subscriptions for the photograph, and in so doing he took dominion over it. Therefore defendants were liable to pay, and the verdict must be in plaintiff's favour for the amount claimed, with costs.

## News and Notes.

**LECTURES** at the R.P.S. Exhibition New Gallery.—The following are the next three fixtures: Saturday, October 13—"Corsica: the Isle of Unrest," by Chas. B. Howdill, A.R.I.B.A.; Monday, October 15—"By-paths in India" (unfrequented places in the Madras Presidency, etc.; buildings, people, and scenery), by F. Dunsterville, F.R.P.S.; Thursday, October 18—"All at Sea with a Hand Camera," by F. J. Mortimer, F.R.P.S.

**THE Southampton Exhibition.**—This exhibition, which is the last of the "Southern" shows, is to be held from December 11 to 15. The judges are Reginald Craigie and H. Snowden Ward, F.R.P.S., in the pictorial sections, and F. Martin Duncan, F.R.P.S., in the technical section. Bronze salvers are offered as awards, and under the new arrangements those exhibitors desiring also to exhibit at Southsea and Hove Exhibitions are only required to send one entry form and one payment of fees, the societies paying all carriage expenses between the three exhibitions, and offering a special salver as an award for the best collective exhibits entered. Entry forms can be obtained from the Hon. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.

**NOVEL Cinematograph Show.**—An American novelty for the amusement of the public has started its career at 165, Oxford Street. It is a new method of showing biograph pictures of interesting places. The spectators take their seats in an exact replica of a Pullman car, and through the windows they will view the ascent of a Swiss mountain, or enjoy a visit to any other beauty spot. Realism is to be a feature of "Hale's World Tours," for the Pullman will appear to move. It will turn corners, and its wheels will revolve, while the passengers, free from the dangers of a collision or a fall over a precipice, will admire the scenery through which they seem to be passing.

**THE Photographic and Engraving School** at the Regent Street Polytechnic opens its session on October 16 at 8 o'clock by a lecture by the principal, Mr. Howard Farmer, on "The True Action of the Levy Screen," followed by a display of animated photographs. Mr. Farmer is always original in his treatment of a subject, and if anyone can make the theory of half-tone reproduction interesting he is the man. The full prospectus of the "Poly." classes should be obtained by all those about to take up a business career in photography or thinking of improving themselves in special branches. The classes provide instruction in every photographic process and in photo-engraving and three-colour. The specimen-book of students' work in the printing department of the "Poly." contains some excellent examples of three-colour half-tone by those studying under Mr. Farmer.

A **LARGE** book treating on photography in the popular way will shortly be published by Messrs. Methuen. The title is "The Complete Photographer," and the author, Mr. R. Child Bayley.

An exhibition by a small group of artists is to be seen at present at the Ryder Gallery, 47, Albemarle Street. It consists chiefly of small canvases, and is throughout of sufficiently sound quality to deserve a more than ordinary degree of consideration. The most memorable contributions are the delicate twilight studies. "Moon-rise.—Picardy," "Sand-dunes at Cimiez," and the brilliant little landscape, "The Mill Stream, Montreuil," by Mr. W. Llewellyn.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE OZOBROME PROCESS.

To the Editors.

Gentlemen,—I was pleased to see the very full and excellent report of the Rev. H. W. Dick's lecture to us on "Ozobrome." There is a little error, which is perhaps a misprint, on page 786, middle of second column. You say: "In the case of subjects with too much contrast (in the bromide print) a little acid added to the pigmenting solution would remedy matters." This should be "a little alum." Additional acid, I find, has the effect of causing the lighter gradations to wash away in development.

With regard to the suggestion to add ammonia to the solution to increase the contrast, I saw Mr. Manly since the lecture, and he tells me he considers it is a mistake to use ammonia for this purpose. He recommends citrate of potash. I suppose the ammonia would have the effect of converting the ferricyanide of potash into ferrocyanide.

I see you suggest that the bromide print and pigment plaster, after being squeegeed together, should be put under pressure, but Mr. Manly, in the book of instructions, says they should be placed upon blotting paper, or hung up until ready for development. I think this is a better plan, as there is no necessity for pressure at this stage, and I suppose that if the adhering papers are put separately between blotting paper under pressure they would dry too much, and the pigmenting solution would not act so thoroughly as if they were left damp. In the transfer process, however, after squeegeeing to the transfer paper, some light pressure is advisable to ensure adhesion.—Yours sincerely,

S. C. PUDDY.

Hon. Sec. North Middlesex Photographic Society,  
Arrington House, Crouch Hill, N.

### AUTOTYPE THREE-COLOUR PRINTS.

To the Editors.

Gentlemen,—We have read with much pleasure the appreciative notice of our exhibit at the New Gallery appearing in your current number, but would call your attention to one little point, which, unless elucidated, may lead to misunderstanding. You state: "Two specimens are shown of the Autotype three-colour printing on the trichrome tissues." As a matter of fact, there is only one; the second coloured picture being the original painting, from which our trichrome copy has been produced.

If your astute reviewer has been deceived into thinking both coloured pictures are trichrome copies, we feel immensely flattered. We believe this is the first time that an original and copy in trichrome tissues have been exhibited together, and we purposely did so on this occasion to demonstrate how closely our process can imitate the original.—Yours faithfully,

C. SAWYER.

The Autotype Company.

[We must express our regret that we overlooked the commendable step taken by the Autotype Company in exhibiting original and copy side by side. In the absence of a catalogue at the time of examining the prints, the close similarity certainly led us to suppose that both were three-colour prints. The Company has at once our regrets and congratulations.—Eds. B.J.P.]

### MR. J. T. SANDELL—AN APPEAL.

To the Editors.

Gentlemen,—I feel sure that many of your readers will be sorry to hear that Mr. J. T. Sandell—the inventor of the "Sandell" plate and cristoid film—is stricken down with a serious illness, aneurism of the aorta, and in need of help. The doctor says that if he does get about again he will never be able to do any work.

His voice is almost gone through paralysis of the vocal chords, he is now lying in a perfectly helpless condition, necessitating constant nursing and attention.

He has a young and devoted family, but only one, the eldest is able to give any pecuniary help, and that (as he is only starting in life) is not sufficient to provide more than the command necessities.

I have known Mr. Sandell many years, and can testify to readiness to help anyone in difficulties, photographic or other, and he never thought it a trouble to travel any distance to a photographic society to give a lecture or demonstration.

If you would be good enough to make this known, through columns of your paper, I am certain that many brother inventors, photographers, and others, who have known Mr. Sandell, will, in his hour of need, to help one who has always been ready to help others.—Yours truly,

J. B. B. WELLINGTON.

The Leys, Elstree, Herts,  
October 4th, 1906.

[We are glad to see that the London and Provincial Photographic Association at its supper subscribed £5 2s. in response to an appeal by Mr. T. K. Grant. We have received one or two donations, and we will acknowledge with others next week.—Eds. B.J.P.]

### THE COST OF PRODUCTION.

To the Editors.

Gentlemen,—Reading through your issue of the 5th inst., paragraphs appeal to me as worthy of consideration, the one relating to the relative cost of "Ozobrome" processes, and the one among "Answers to Correspondents," "Starting in Business."

It seems to me that many amateur photographers have been induced to become professionals through a false idea of the cost of photographic production, and upon entering business they have found their charges upon these notions, and in their turn, more serious and established photographers have been compelled to reduce their prices similarly, so that at the present time the photographic student that pay well are few, and those that have difficulty in making a living are many.

The masterly article given by F. Dundas Todd to the National Convention in the United States, and recently reported in columns, should prove of immense value to many professions providing them with a reasonably accurate guide to what constitutes "cost," and of the little shares of big expenses that have to be borne by the orders that go through, and the proportion of "indirect expenses" will in most studios be found to run up to 50 per cent.

When studied in this connection, the cost of a 15 x 12 negative will be:—

	s.	d.
Material for transparency.....	2	½
Time .....	3	
Material for enlarged negative.....	1	6
Time .....	8	

Proportion of waste (15 per cent.).....	2	7½
Indirect expenses (50 per cent.) .....	5	½
	1	4

Total cost .....

And the bromide enlargement

Material .....	4	4
Time .....	6	½
	4	

Proportion of waste (15 per cent.).....	10	½
Indirect expense (50 per cent.).....	1	½
	5	½
	1	5½

In the above estimate the cost of material in each case is reckoned as the small discounts given to the profession are insufficient to cover the cost of chemicals.

Waste.—I think that 15 per cent. for waste is about an average for an all-round studio which is called upon to do all descriptions of work; but, of course, the waste varies considerably in different studios.

departments. In developing and simple printing about 1 per cent., up to printing portrait enlargements in carbon by double transfer, where this is only occasional work, 50 per cent.

Indirect expenses at 50 per cent. do not seem excessive after considering the article previously referred to, and it will be noticed that the relative cost of the two processes has not greatly changed.

These reflections are intended as food for the professional photographer, as well as those who, like "Starting in Business," have a wrong idea of the photographic profession. Probably many who read this have much more accurate estimates of cost than I have given, and I am sure they will see that it is to the general advantage to disclose them.—Yours faithfully,  
SYDNEY ALF PITCHER.  
College Court, Gloucester, October 6, 1906.

## DIRECT-COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—In connection with your article on Baron von Hübl's experience of our "Uto" paper in this week's JOURNAL, it may interest your readers to know that we have been successful in simplifying the manipulations in connection with our "Uto" paper so that it is now no longer necessary to sensitise the finished paper at all, all the necessary sensitisers being introduced in the paper during manufacture. The colours bleach out very regularly and rapidly; the finished print being sharper and more correct in colour than previously. The importance of this improvement will be recognised immediately by all users of the paper.

It may further interest your readers to hear that we have joined interests with the "Chromophot" group who hold the Szczepanik patents in colour photography, and that all manufactures relating to direct colour photography by the combined Smith-Merckens-Szczepanik patents will be placed upon the market as "Aneto" manufactures.

A direct-colour plate will be placed very shortly on the market, and our "Uto" paper will remain on the market as Aneto Manufacture "Uto" Brand.—Yours faithfully,

DR. J. H. SMITH AND CO.

Zürich, October 6, 1906.

## THE SENSITOMETRY OF PLATES.

To the Editors.

Gentlemen,—Mr. Kenneth Mees' letter, I am afraid, does not help me any further with regard to the absence of ultra violet in the acetylene standard as compared to daylight. I quite understand the action of the blue-violet filter in reducing curve B to curve A. This was quite clear from the paper in the "Photographic Journal," March, 1906, but I cannot see how increased depression or absorption of the red end can give us what is non-existent—namely, the ultra-violet. This is my crux.

Possibly my objection is purely theoretical, but it is intensified by careful consideration of the above-mentioned paper, where the "large amount of ultra-violet in daylight" is clearly shown. Again, Eder states that the effect of the ultra-violet is 38 per cent. of the total effect of a daylight exposure ("Beitrag, Theil II," p. 161). Further, the valuable examination and the remarks on the absorption of filter-yellow-K, by Messrs. Mees and Wratten, in your issue of 28th ult., do not tend to make me alter my opinion, for if this dye is such a great improvement the ultra-violet must be of considerable importance.

I am grateful, however, to Mr. Mees for his help, and particularly on the fog question.—Yours faithfully,  
London, E.C.

ARTHUR GASCOIGNE.

## PHOTOGRAPHIC RESEARCH.

To the Editors.

Gentlemen,—The intentions of the Photographic Convention in offering grants of money in aid of photographic research are most admirable, for the want of capital is a very effectual hindrance to research work. The second condition, practically prohibiting the expenditure of the grant on permanent pieces of apparatus, seems, however, to me to afford a very effectual barrier to applications for

the grant, for want of apparatus is just the one thing that most often bars the way in a promising investigation. Surely the Convention do not actually prefer that the money should be expended in impermanent apparatus, or in perishable materials. The acquisition of, say, a spectroscope, or a microscope, or a photometer will not only facilitate the carrying out of some one research but will encourage further work on the same, or, perhaps, quite different lines. From any point of view, expenditure on apparatus of permanent value is a better investment than expenditure on temporary expedients that will be of no further use, or on materials that are destroyed by use. As a matter of fact, the private investigator does not feel the cost of materials and of temporary "fit-ups" very much, for the latter cost little beyond time, while the expenditure in the former is spread over a long period. The thing that checks him most is the expenditure of a lump sum of, say, £5 on a photometer or some other piece of apparatus. Too often he simply cannot do it, and then he either abandons the research or has to publish results in an incomplete and, very frequently, misleading fashion.

If the Convention feel assured that a proposed investigation is worthy of a grant at all, it seems to me that the expenditure of that grant on permanent apparatus that will be of further value in the future should give them cause for satisfaction rather than otherwise. In any case, I believe this is the view taken by others who make grants to facilitate research.—Yours faithfully,  
Blackheath, S.E.

C. WELBORNE PIPER.

## THE STABILITY OF PYRO AND SODA DEVELOPING SOLUTIONS.

To the Editors.

Gentlemen,—The article on pyro-soda developers, by Mr. Bennett, and your comments thereon, have afforded me some interest, inasmuch as your experience coincides almost exactly with mine.

Until a few years ago, I was in the habit of keeping the sulphite and carbonate together in solution, and was insistently worried with negatives varying in colour and quality, as the developer became the least bit ancient. Suspecting the cause, I varied my method, and kept the sulphite and carbonate separately in solution, with very little improvement in results. In each case, after the solution became a few days old, the colour of the negative image would degenerate from the original black to a dirty greenish-brown.

Now, for the past four years I have adopted a formula which, strangely enough, corresponds almost exactly to the one you publish in your editorial note on page 760 (September 28). It is as follows:—

No. 1.—Sulphite of soda .....	6oz.
Metabisulphite .....	1oz.
Pyrogallol .....	1oz.
Water up to .....	50oz.
No. 2.—Soda carbonate .....	12oz.
Water up to .....	50oz.

Using equal parts, either undiluted or with further addition of water, to result desired.

This developer I have found quite reliable after fifteen months, being the longest interval, up to the present, between making up the formula and using up the last few ounces, which, by the way, used side by side with newly-made developer, gave results comparable in colour and showing no abatement in energy.

"An ounce of practice is worth a ton of theory," to use an old saw. I have compared this formula with many of the newer developers, and still prefer it for negative making.

Finally, I am always careful to dissolve the sulphite first in tepid water, adding the metabisulphite when dissolved, and finally, when quite cold, the pyro.—Yours faithfully,  
163, Sumatra Road, West Hampstead, N.W.

S. A. HERBERT.

To the Editors.

Gentlemen,—I have read with much interest your last two articles on the subject of pyro-soda developer, but one or two items somewhat puzzle me (and no doubt others), and I should be grateful for your replies. Bringing the proportions of the developer (as finally advised in this last "B.J." number) down to 1 oz. of solution,

I make out it is composed of 4 grs. pyro, 45 grs. soda carb., 22 grs. sulphite,  $5\frac{1}{2}$  grs. metabi. to 1 oz. water. Is this the usual working strength; 4 grs. pyro per ounce being much above the usually advised strength of the various platemakers, which is from 2 to  $2\frac{1}{2}$  grs. pyro per ounce of developer (mixed)? Though I admit it is the H. and D. standard formula, I have always understood that 25 per cent. to 50 per cent. of the pyro used is the maximum amount of metabisulphite potassium advised, a greater quantity than that slowing the plate; yet your formula appears to contain almost 50 per cent. more than the amount of pyro. The proportion of carb. soda (45 grs. to 4 grs. pyro), even deducting 6 grs. as being neutralised by the potass. metabisulphite is 10 to 1 to the pyro. This of itself would make the developer very quick-acting. I note some of the formulae in general use, such as Seed Plates, Kodak Co., and others, advise a proportion of only 4 or 5 or 6 soda to 1 pyro. For some development, such as the old formula of Kodak machine (1.3 gm. pyro, 6.5 soda, 7.8. sulphite per 1 oz.) at temperature 65 degrees of 6 minutes, is your formula (and if so, diluted to what strength?), and improvement. The time would vary too. Please understand I in no way intend to criticise, but simply to ask your further guidance re the formula. Thanking you.—I am, yours faithfully,  
D. GREENWAY.

Waratah, 107, Dartmouth Road, Cricklewood, N.W.

[The quantity of pyro is increased to 4 grains and the carbonate to 45 to give sufficient density in a reasonably short time. As explained in our notes, the formula is relatively slow compared with others, even though it contains an excess of alkali. Also, though it contains more materials it is more economical, as it can be used many times in succession. None of the carbonate is neutralised by the metabisulphite, which is only used in sufficient quantity to neutralise the sulphite. There is no free sulphurous acid present, and this is one of the essential features of the formula. The effect is probably about equivalent to that of the old Kodak formula—that is to say, 6 minutes at 65 degrees F. is about the right time of development. The results will, however, be absolutely clean black and white, and probably four or five rolls of film in succession can be developed in the same solution, if the time of development is increased by a minute in each case. All should then be equally stainless. If you read our notes carefully you will see that keeping quality and reliability are important features claimed for the new formula, in addition to its non-staining and economical properties. Other formulae that keep fairly well give stain in time, and some that give quite clean images when fresh will not keep. We are doubtful as to metabisulphite slowing the plate, and also very doubtful as to metabisulphite existing at all in our formula. We are not at present prepared to discuss the chemistry of the subject.—Eds. B.J.P.]

#### EDER'S "JAHRBUCH" AND THE "B.J. ALMANAC."

To the Editors.

Gentlemen,—In reviewing Dr. Eder's "Jahrbuch" you say:—"To the more recondite branches of photography, such as photochemistry, Russell effects, spectroscopy, Dr. Eder is prepared to devote a number of pages, which in this country would seem out of proportion to the number of persons able to make use of such information. Our own feeling in preparing the 'Epitome of Progress' in the 'B.J.A.' is that such persons may be presumed to have the original articles for their reading." I beg to submit that a great number of persons in Germany are deeply interested in scientific photography and photochemistry, and that the number of journals, where such articles appear, is too large for any one interested in this matter to read them all. Of course in having the attention turned to any such publication, it will be necessary to get hold of the original article which, without the "Yearbook," might never have come to the knowledge of all interested ones. And then, what precious books of reference those Eder's "Jahrbücher" since 1887! No, let us have by all means these "Jahrbücher" just as they are and the "B.J. Almanacs" as they are. Both of them have their wide several spheres of utility, and I, dear Mr. Editor, for one, would not like to be without either of them.—I am, dear Sir, yours very truly,  
Dresden, October 8, 1906.

RICHARD JAHR.

## Answers to Correspondents.

- \*\*\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \*\*\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \*\*\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- \*\*\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

- J. MacMahon, 502, Union Street, Aberdeen. Photograph of the Tables Set for Banquet in Strathcona Hall, Aberdeen.
- P. Swift, 280, Waterloo Road, Burslem. Photograph of Burslem Port Vale Football Club.
- L. Turgill, 106, New Oxford Street, W.C. Photograph of Mrs. Brown-Potter and her Two Dogs.
- S. W. Babb, 2, Hengist Villas, Southwood Road, Ramsgate. Photograph of a Dog and a Cat, the former Dressed Up and Standing on its Hind Legs, the Feline Paws Resting on the Handle of a Perambulator Containing the Cat, a so-so Doll.
- W. Cooper, Greenfield House, Station Lane, Heckmondwike. Photograph of Dewsbury Football Team, 1906.
- T. A. Brook, Beauchamp Cottage, Habberley Road, Bewdley. Photograph entitled:—"Sunset, Spring Grove Farm, Bewdley."

**COPYRIGHT.**—If a photograph is copyright, can it be printed (or reproduced) in more than one paper without payment for each reproduction? For instance, if I send a photograph to a paper, or magazine, and it is accepted, could other papers have the same photograph in without a payment for same?—H.

Certainly the other papers cannot. Publication in them is an infringement of copyright, and if your copyright has been registered prior to such infringement you can obtain penalties. You will find the whole law of the subject in the ALMANAC for the current year.

**BLUE PRINT.**—I enclose you a print obtained from a formula as follows:—

Citrate of iron and ammonia, 1 oz., dissolved in 4 oz. water.  
Ferricyanide of potassium, 1 oz., dissolved in 4 oz. water.

Take 1 drachm of each.

and shall feel obliged if you will inform me, through your column, the formulae for the other colours, which, I understand, can be produced, such as red, brown, green, and purple.—GEORGE HILL.

The various toning formulae are not at all satisfactory. For greenish-black prepare: Borax, 30 grains; water, 1 oz.; add sulphuric acid, drop by drop, till the liquid just reddens litmus paper, then add 10 per cent. ammonia until the red colour commences to change. Now add 4 grains of powdered catechu. Shake well and filter and tone the blue prints in the solution. For black to brown tones, place the dry print in:—liquid ammonia, 6 mins.; water, 1 oz.; and when bleached place print in tannic acid solution, 9 grains per oz. Both processes degrade the print. Why do you not use carbon for the colours you name?

**COPYRIGHT GROUPS.**—During the month of August I photographed two cricket teams. I received no direct order to do so, but in each case about two members said they would have a copy. I took them, and not a single copy was ordered in either case until I showed a finished copy to one of the members. Then, or at a time, most of the two elevens had a copy, though not all. Is the copyright mine? I ask this because in one or two cases the members are having enlargements done by the — with coupons. Can I stop it? This is a very small place to get a living, and, of course, this hurts my trade.—MAGNET.

If you have registered your copyright you can obtain penalties for any subsequent infringements such as that you name. If you have not registered you can do so now, and stop further copies being made. We should advise you to place the matter in

solicitor's hands, or, if you are a member, in those of the Professional Photographers' Association. So long as it can be shown (1) that you were not ordered to take the group, and (2) that no special favour was made of allowing you to photograph the team—you can sustain your proprietorship in the copyright.

**POSTCARD MACHINE.**—Having very often a lot of postcards (bromide) to print I have devised a hand machine for the purpose. I know there are several machines for the purpose on the market, but this seems to me to be much handier than any I have seen. It certainly could be made much more cheaply, and I have printed at the rate of over 500 an hour. It is simply connected in place of an ordinary electric lamp, and is worked by one hand. Will you kindly tell me if you think there would be a market for such a machine, and if so what steps I could take to sell it? Could you tell me any firms likely to adopt it?—R. H. F.

We should say the market is already over-supplied with apparatus of this kind. The possibility of getting yours taken up depends on its speed of working and on its cost of manufacture. You must know the existing machines, and be better able to judge of the powers of your own to compete than we are.

**ALPHA.**—We do not see that you can do anything in the matter, as the copyright in the picture was not yours. The only advice we can give you is to be more careful in future of the "friends" you employ to make your enlargements.

**COPYING PAPER PRINT.**—I have occasion to copy a print which is made upon a rather rough surface paper. In my enlarged negative the face is most objectionable, owing to the enlargement of this rough surface. Is there any method by which I can prevent the grain of the paper from showing so plainly, or at any rate, lessen the effect.—B. A.

The obtrusiveness of the grain of the paper may be reduced to a great extent by judicious lighting when the picture is copied. Hold the picture at a window at different angles, and at some the grain will scarcely show at all. That is the angle at which the picture should be copied. With very rough papers nearly a direct front light may be necessary.

**DEVILS IN PHOTOGRAPHY.**—I am having trouble with my etching-bath (perchloride of iron, for etching photogravures) in the form of what I believe are called "devils," deeply etched holes, generally fern pattern. I have been told that in some cases this can be got rid of by putting a little ammonia in the etching solutions; but in my case this has made no improvement whatever. I should be glad if you could give me a remedy.—A. COOPER.

If sufficient ammonia has been added to leave just a slight precipitate, then the devils are not caused by the perchloride bath, but they are probably caused by the carbon negative being improperly in contact with the metal, and thus allowing the perchloride, after penetration through the film, to spread in the manner stated. Try squeezing the carbon negative down very carefully, avoiding any air-bells, and allow to remain under pressure for fifteen minutes before attempting to develop.

**WAXY STUDIO ROOFS.**—Could you kindly recommend me a reliable formula for waterproofing leaky studio glass roof?—TROUBLED.

See note on the subject in "Ex Cathedra."

**B. (South Wales).**—Moore, Desaulles and Co., Wordsley, near Stourbridge.

**BRIGHT PORTRAITURE.**—I shall esteem it a great favour if you will be kind enough to help me in my query. I am thinking of taking photographs by gaslight, and wish to know the best and most convenient method for same. The size of photographs I require is 2½ x 1½, say at an exposure of four to five seconds, with special rapid plates.—A. N.

If you write to a maker of apparatus for the purpose, such as Fallowfield, the Tress Co., or Sharp and Hitchmough, you will see the kind of lamp to buy.

**WASHING PRINTS.**—I have occasion to finish 120 postcards at one time, and should be glad if you will answer my query in your next issue if possible. I have a large basin, holding three or four gallons of water, that I use for washing (after fixing) purposes, and I allow running water (through tubing to give force) to run on them for one hour, moving them every few minutes. No outlet to basin, and only over the sides. It is said that hypo is heavier than water, so will sink to the bottom of basin. I

thought I would bore hole in bottom. Do you think it would free them better in this way, of course, allowing water to run the same for one hour?—O. I. C.

There will be no advantage in having the hole at the bottom. The best thing you can do to improve matters is to transfer all the prints every now and then to a fresh basin of water, turn them over, and put them back into your washer, having filled it with clean water in the interval.

**PATENT RIGHTS IN THE MOON.**—Will you please inform us through the medium of "Journal" whether the "moon," as a photo-accessory, is patented, or whether anyone can use it?—J. and E. WILSON.

You are at full liberty to use the moon as a background, either at its full or during any of its phases.

**OLD LENS.**—I should esteem it a great favour if you would kindly give me an answer to this letter in your journal. I have just bought a lens which bears the name of E. Buxton, Church Street, Minorities, London, E., and is named on the box: "E. Buxton's Improved Achromatic Lens." The instrument is about 4in. diameter, with a lens only at the back, which, I believe, is single, but I cannot get it out to see; there is no lens in front, but there is a thread inside the front aperture, which is about 2in. diameter; there is no place for stops, and what I am thinking is that there should be some combination lenses to reduce focus to cabinet and different sizes. Can you tell me if this should be so?—R. T.

Without seeing the thing we can express no opinion upon it. It is evidently incomplete, and is probably a lens that was made some forty or more years ago and quite out of date now. Why not write to the one whose name and address it bears. You will then learn whether he is in business still.

**POSTCARD.**—In our next.

**F. CORE.**—We have had no experience in buying the material, but we may refer you to the paragraph on fireproofing fabrics in "Ex Cathedra" a week or two ago.

**NON-STAINING PYRO.**—I have been greatly interested in your articles and leaders upon the above in issues of September 28 and October 5, and can quite confirm the staining with old mixed sod. sulph. and sod. carb. I had some by me, and thought I would try it upon some negatives after reading your first article; they were interiors, and took rather a long time to develop, and the result was the worst case of yellow stain I have ever seen. The same pyro sol. with fresher mixed sod. sulph. and carb. gave quite normal results upon the same class of subjects. Will you kindly tell me: (1) The best way to remove the dense yellow stain? (2) A chistoid film is stained yellow in places through the parts not being under the hypo. What can be done to it? (3) I had made up the sulph. and metabisulph. sol. as recommended by you on September 28, viz.:—4 oz. sod. sulph., 1 oz. potassium metabisulph., in 40 oz. water, and now I notice this is the wrong strength; therefore I must dissolve 4 oz. sod. sulph. and 1 oz. potassium metabisulph. more in the sol. How is the best way to do this?—as sod. sulph. takes so long to dissolve in cold water, and I think for a sol. of this strength it would be extra difficult. (4) The great recommendation to my mind is that it can be used for amidol. What proportion of the neutralised stock sulph. do you use? It would have been better, I think, had the formula worked to ½ oz. and ½ oz. of pyro, say 120 gr., instead of 160 gr.—i.e., easier to weigh—as two or four would empty the bottle.—

WEDEE.

(1) We should try an alkaline bleaching powder mixture, as given on page 955 of the "Almanac." (2) Nothing, we fear. (3) Dissolve the sulphite in warm water and add the metabisulphite when cold. (4) The stock solution can be used to give 20-25 grains soda sulphite for every 2 to 3 grains of amidol.

**ARMY PHOTOGRAPHERS.**—Will you please inform me through the B.J.P. information as regards getting on the photographic staff of the Royal Engineers.—G. BUTTER.

We are under the impression that the photographic work is mostly done by soldiers who have enlisted. You may possibly be able to get some information on the subject at the recruiting department, Trafalgar Square.

**ARTIFICIAL LIGHT FOR STUDIO.**—I beg to ask if you will favour me by answering the following, as I have taken the above premises, and am afraid I shall not be allowed to build studio at back? I would like to know if I could get satisfactory results for middle-class work by a large gas lamp, as there is no electric light in town. I might say I have a splendid room for same (18 ft. by 11 ft.), or is there any means of working electric by a battery? Would be greatly obliged if you could give me the name of firm supplying lamp suitable, and your opinion.—STUDIO.

It is possible to get the electric light from a battery, but you would find it a great trouble in practice; moreover, the fumes from it would be an annoyance, unless it were placed out of doors. Flash light, also acetylene, could be employed. Gas can also be used. The Tress Company, 42, Oxford Street, W., have a gas-light appliance for studio work.

**E. ABRAHAM.**—(1) We should have thought anyone would know how to manage his own business better than we could tell him. In your long letter you complain that the man you have, who does all the retouching, developing the negatives, the "copying jobs," does the operating, and attends the shop when you are out, etc., is too slow. What can you expect for the princely salary of twenty-five shillings a week? (2) Lady receptionists and retouchers are usually paid from a guinea to a guinea and a half and upwards a week, according to ability. (3) As the water is used for business purposes, the company will require it to be paid for according to its consumption; therefore it will be to your interest not to waste more than can be avoided.

**RATIO OF STOPS.**—I am using a 1.1 plate lens in the studio, maker's name Darlot, Paris; the stops are marked 15-30-40-50-60, sixty being the largest aperture. Now, I should like to find out the equivalent to the F seriate for light-testing; kindly let me know through the Journal.—LENS.

Probably the numbers represent the diameters in millimetres, but the best thing to do is to first ascertain the equivalent focus of the lens and then divide the size of the stops into that, and that will give you the ratios. For example, if the focus of the lens be, say, twelve inches, and the diameter of the largest stop three inches, the ratio will be  $f/4$ , as it is one-fourth the focal length. Other stops are calculated in same way.

**SITUATION IN FRANCE.**—It is my intention to seek a situation in a photographic house in France or Switzerland; could you kindly recommend me the best advertising medium for that purpose?—W.S.

"Photo-Revue," 118, Rue d'Assas, Paris; and "Revue Suisse," 23, Escaliers du Marche, Lausanne, Switzerland.

**DEVELOPER FOR BROMIDES.**—Which do you consider the best developer for bromide enlargements, either ferrous oxalate, metol and hydroquinone, or amidol. I am anxious to get rich blacks and pure whites, and irrespective of the extra trouble, do you think the first one above gives you this better than the other two quoted, and of M.Q. and amidol, which do you consider gives you the richest blacks? I do not like the grey-looking prints one often sees.—BROMIDE ENLARGEMENTS.

For a strong intense black there is no developer to beat ferrous oxalate. If you object to the acid baths necessary, perhaps the ferrous citrate developer of the Rotary Photographic Co. would suit you. Next to iron we should place amidol for vigour and black colour. But it should be used freshly made.

**L. S. (Sydney, N.S.W.).**—1. Shellac or a mixture of laes. 2. Yes. 3. It will be no infringement of the patent to prepare it for your own use. You can obtain it from the Adhesive Dry Mounting Co., 27-28, Fetter Lane, London, E.C.

**GLAZING P.O.P.**—1. Kindly inform me in your next issue the reason P.O.P. prints won't leave pulp-slabs and plate-glass. They have been well cleaned. Do they want rubbing over with some solution? 2. Is there a glazing-slab made from celluloid, and who is the maker?—ROBERTS.

1. It is always advisable to prepare both the pulp-slabs and plate-glass, and one of the simplest things is an ounce of ordinary resin ointment dissolved in half a pint of warm turpentine. Rub this over the glass, then polish with a clean linen pad. The

prints will also strip easier if immersed for five minutes methylated spirit and squeegeed, all dripping on to the glass. 2. A special squeegee pad is made by the Altrincham Rubber Co., Mossburn Buildings, Altrincham, but we cannot say whether this is celluloid or not. Almost any large dealer will supply thick celluloid, either matt or polished, which can be used for this purpose.

**SEPIA BROMIDES.**—Would you kindly let us know through your columns the best chemical for making sepias from bromide prints?—THE AMERICAN ART CO.

Use one of the many sepia tones or the formula on page 978 of the "Almanac."

**PORTRAIT SWINDLE.**—A gentleman at this place has sent his photograph for one of Tanqueray's life-size crayon portraits, with the required amount of 10s. for packing, shipping, and railway charges to his home, and another 10s. for a frame, as it was got damaged without a frame, and when the picture arrived there was 4s. 6d. more to pay for carriage. The gentleman refused to pay, as all the charges had been paid. It was taken back to the station. Would you kindly advise what would be the best course to take in the matter. They value the crayon portrait at £4.—E. MOORE.

Your friend had better pay the 4s. 6d. if he wants the picture. He has been "had" by this ancient fraud, and we would advise him either to resign himself to the loss of the £1, or pay up the remaining charges with as good grace as he can.

**PHOTO INDUSTRIE.**—We do not know that the camera is being made. Your most likely source of information is Messrs. Sang, Shepherd and Co., Gray's Inn Passage, High Holborn, London, W.C.

**TONING BROMIDES.**—Can you recommend a formula for toning bromides a good cool shade of brown, something near "standard brown" of carbons. I have tried several of the made toners on the market, but with all I get such a "sandy" brown. I want a cooler shade than I now get.—AMATEUR.

Several formulæ were given in our issue for August 10 (page 625), which entail the use of uranium, and these followed acidulated sodium sulphide, both give deep browns, which are stated to last at least four years. Possibly the use of hypo-alum bath with silver nitrate would give the desired tone. This is:—

Hypo .....	3ozs.
Powdered alum .....	130grs.
Water .....	20grs.

Dissolve and add:—

Silver nitrate .....	4grs.
----------------------	-------

Heat two or three times to 140 degs. Fahr., and allow to cool. For use the bath should be from 100-120 degs. Fahr. The developer has some little effect on the toning with sulphide and amidol gives the coolest tone, then metol-hydroquinone, then hydroquinone. The sulphide formulæ are given in our issue for August 17 (page 646).

**DEVELOPER.**—We have not used any special formula, usually that of the plate-maker, or the one on page 949 of the "Almanac."

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The Royal Exhibition and Salon close on Saturday in next week, October 27.

A Society of Colour Photographers is in process of formation. A preliminary meeting was held at the office of the BRITISH JOURNAL Tuesday last. (P. 851.)

The fund on behalf of Mr. J. T. Sandell amounts, we are glad to say, to £75 14s. 6d. Further donations may be sent to ourselves to Mr. J. B. B. Wellington. (P. 831.)

Professor E. Walter Maunder will deliver the Traill-Taylor Memorial lecture next Tuesday on "Photography in the Work of Greenwich Observatory." (P. 831.)

Herr W. Weissenberger, in Eder's Jahrbuch, records the success attained in preserving sulphite with mannite, etc. (P. 829.)

A German writer has pointed out how certain optical defects may be advantageously employed in portrait photography. (P. 827.)

M. Demachy has worked out and improved on the Rawlins "oil" process. His new method of working is described, from "Camera Work," on page 825.

Still another patent for catatype printing has been taken out by N.P.G., of Berlin. It is to be assumed that a commercial catatype press—that is, one printing without light—will be on the market very long. (P. 833.)

Some notes on the selection of accessories for the studio appear on page 823.

Etching machines for photo-engravers are being offered in several terms. Some notes on the now available machines appear on page 832.

## EX CATHEDRA

### Residues.

Many persons, so we gather from letters we at times receive, find a difficulty in precipitating the silver from the washing waters of prints prior to toning, particularly from gelatine papers. The usual precipitants employed for the purpose are chloride of sodium (common salt) and hydrochloric acid. Now it so happens that both these materials are, to a small extent, solvents of chloride of silver although they are precipitants of it. Therefore if a larger excess of it be used some of the chloride thrown down will be re-dissolved and will remain in solution. As a matter of fact, some P.O.P.s contain very little free nitrate of silver, its place being taken by organic salts of silver that are insoluble in water, and therefore little is to be found in the washing waters. Consequently if a large excess of the precipitant is added that little may be re-dissolved and will remain in solution and consequently be lost. The organic salts, or that proportion of them that is not reduced by light, are dissolved out in the fixing bath, and it is from that they may be recovered. The usual precipitant of the silver from fixing baths is the sulphide of soda—liver of sulphur. This again, if used in excess, is also a solvent of the sulphide of silver thrown down. Modern papers, as compared with the old albumen paper as sensitised by the user, contain but a small amount of silver, though sufficient to produce good prints, hence there is but little to be recovered in the form of residues, and if this little is re-dissolved by the precipitants used it is, of course, lost altogether. Disappointment is frequently expressed at the small return made by refiners for the wastes sent to them for reduction, particularly the ashes from paper. Now, if the paper in the first instance contains but little silver it follows there can be but little to recover from its ashes, and this does not seem to be fully realised by some. It may be a question for the consideration of small consumers of P.O.P.s as to whether the residues are really worth the trouble of saving, seeing the present small value of the silver when recovered. At the present time the price of standard silver is but two shillings and eightpence the ounce, and that is higher than it was a short time ago, and, further, the metal recovered from photographic wastes is seldom so good as that. With those who work on a large scale the case may be different.

### Cost of Production.

Many have been tempted to start in the photographic portrait business with a knowledge of the mere cost of the material, without taking anything else into consideration. They have learnt that the cost of plates for, say, cabinet pictures is so much, and the cost of a dozen pieces of paper is, again, so much, and from that they calculate the profits on a dozen

portraits to be a very substantial one. It is this idea that has led so many to enter the profession, and a very large proportion of them, thus induced, have found things by no means so rosy as they fondly imagined. In our issue of a fortnight ago we estimated the cost of materials alone for making carbon enlargements by the usual method from a small negative, and by the "ozobrome" process. This was for the bare materials; the value of the labour was not, of course, taken into any account whatever. Last week a correspondent estimates the cost of making an enlarged negative, 15 by 12, including cost of material, time, waste, and indirect expenses, at four shillings and fourpence. This we should consider far too low if the work were done, as an occasional thing, by the newly-fledged photographer. We find, by reference to the price lists of those firms that make a specialty of carbon enlargements for the trade, and of making enlarged negatives, and keep operators employed on this class of work only, that their prices for enlarged negatives of that size is ten shillings, and if the negative is purchased it is three shillings more. To carry a fair profit it is a little difficult when first-class work is guaranteed to see how the work could be done for less—or, indeed, for so little unless the wet collodion process were employed, as, of course, it is: Those who contemplate entering the photographic profession will do well to read the article by Mr. Dundas Todd which we published a few weeks ago. His estimates were based on established businesses doing fair trades at various prices, and not on those that had yet to be made. When a new business is started by a novice the sitters are few, and often far between, yet the expenses are going on and have to be met, and too frequently there is little capital to meet them. These matters are too often overlooked by beginners before they start in business for themselves.

\* \* \*

**Photographic Salaries.** Circumstances have recently led us to ask:—"Are the salaries paid to photographic assistants getting lower and lower?" If so, there is but a poor prospect for the many apprentices who are now learning the business. The question is one which should be duly considered by those who think of bringing their sons and daughters up to the business. We are led, in the first instance, to these remarks by the letter of a correspondent to whom we replied last week. In the letter he complains that the man he has is slow, and ought to get through twice as much retouching in the course of the day as he does. The man, he says, does all the retouching, develops all the negatives (about a dozen a day), the copying, does the operating, and attends to the

customers when his employer is away, etc. For this is paid the munificent salary of twenty-five shilling week, and complaint is made that he does not do sufficient work. It may be mentioned that the prices charged the employer for portraits are somewhat higher than for many middle-class businesses. On referring to the advertisement column of last week's issue, "Situation Vacant," we were surprised to find almost ridiculous salaries offered for assistants. For example, a pound week is offered for a development assistant who is "able to take large quantities." A similar sum is offered for a developer who is also to assist in printing and vignetting. Twenty-eight shillings a week is offered for an operator and retoucher to manage a branch. Twenty-five shillings for a dark-room assistant, who must be a competent bromide printer and copyist. If such prices as these are to rule for work that requires a certain amount of skill, the outlook is bad indeed for assistants. However, we hope the instances we have quoted are exceptions.

\* \* \*

#### **Fashion Plate Photographs.**

According to a paragraph that has been going round the daily Press during the past week or two, photographic catalogues are to be the draper's novelty during the coming autumn, but only in the case of articles such as boots on a pretty foot, gloves on a well-shaped hand, arm, embroideries and laces, and umbrellas, gowns, costumes, hats, and the like are still to be illustrated by drawings, and not by photography. It has recently been suggested that photography should be used for fashion plates, since the living models would give a better and more truthful idea of what the garment really was than could be gained from the figures out of anatomical proportions so frequently seen. We are glad to understand that the requirements in dress fashion photography is not truth but exaggeration to emphasise certain points. No living being could be found with the ridiculously slender waists that are sometimes depicted in the drawings, and even the retoucher's knife could rarely produce them. Again, such abnormally tall figures, with large faces, are not to be found in life, and such, we are told, are necessary to show off the essential points of costumes. Furthermore, pretty faces are required to set off the "latest things" in hats, so we are told by those who are supposed to know, and these are difficult to find in persons who will allow their portraits to be used for advertising purposes. It is for this reason, we surmise, that photographic fashion plates are not to be employed except to the limited extent above mentioned. Still, we cannot help thinking that they would be more accurate

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1907.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-sixth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,616 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1907 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### **THREE-COLOUR PHOTOGRAPHIC PRINTING PROCESSES,**

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1907 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1907 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—Our publishers ask us to inform Agents that it will be as well to place their orders for copies immediately, as the issue is always booked before publication, and a second edition will not be printed.

able to ladies generally than the ill-drawn things that are now put before them, and we shall not be surprised to hear that photographers discovering profitable business in this branch of work.

#### Measurement of Focal Length.

In "Photographische Industrie" an apparently new method of determining focal length is given. For a single lens we are instructed to focus on infinity and measure the distance from lens surface to screen. Next reverse the lens and again focus on infinity and measure from lens surface to screen. Call these two distances  $a$  and  $b$ , and measure the thickness of the lens and call that  $d$ . Then the focal length is equal to  $\frac{a+b}{2} + \frac{d}{2}$ . This is obviously correct for a simple

single lens in which the nodal space is equal very approximately to one-third the thickness, and the method is so easy that it is a useful one to remember. With doublets the procedure recommended is much the same. The terms  $a$  and  $b$  are found by measuring from screen to nearest surface of lens with the lens normally placed and reversed. The respective thicknesses of the two lenses are then measured and denoted by  $d_1$  and  $d_2$ , and finally the polar separation of the doublet (i.e., distance between the inner surfaces of the lenses) is found and called  $c$ . The focal length of the whole combination is then said to be equal to  $\frac{a+b}{2} + \frac{d_1+d_2}{2} + \frac{c}{2}$ . The accuracy of this formula is, however, not quite so obvious as in the other case. It appears to be assumed, as before, that the nodal spaces of the separate combinations are always one-third the thickness (which is not necessarily the case in combinations), while it is not clear how the quantity  $\frac{c}{2}$  is

derived. Checking this formula may be an interesting exercise for those of our readers who are interested in optical mathematics. It must be remembered that the construction of modern lenses is very varied. We not only find negative and neutral single combinations in doublets but positive combinations with very differently situated nodes. When the nodes for a single combination are coincident or crossed, as is sometimes the case, it appears most probable that the formulæ given above will break down.

#### Demachy on Oil Printing.

From the issue of "Camera Work," to which we referred last week, we reprint, on another page, M. Demachy's article on the Rawlin's process. It will be found "full of wise laws and modern instances." M. Demachy seems to have put the procedure of Mr. Rawlins far behind, and most of his materials and apparatus also; but his own are set forth in a way that brings conviction, and we feel sure that workers will find his suggestion result in greater convenience and more refinement of work. For example, his improved sensitising solution dries in fifteen minutes against the "hours" of that used by Mr. Rawlins. The use of the roller is all but abandoned; the brushes are of special make and special shape; several inks are used on the same print, varying widely in their degrees from opacity to tackiness, and many other important developments will be noted. M. Demachy notes at what an early stage in the process photography "steps out," and he describes the method very truly as "purely monochrome printing on somebody else's drawing—not photography—and the painter's rules must be followed implicitly, and without proper knowledge, or disaster will follow." What a warning is here! In ninety cases out of a hundred a photographer had better stick to P.O.P. and platinum. Let all processes that take artistic responsibility away

from automatic means to place it with the operator, oil-printing is a capital process to fail in, unless it be in the hands of those to whom the photographic basis is of no value in itself; that is to say, an artist by nature and training.

#### INDOOR ACCESSORIES.

If truth and unobtrusiveness are essential features of a good background, the former, at any rate, and as far as possible the latter, are indispensable in an accessory. The present vogue of pictures without accessories is the natural reaction from the elaborate, gaudy, artificial, and often ridiculous objects used in the early days of photography. There is, however, no reason why natural accessories properly used should not be capable of greatly enhancing a photograph as a work of art. Restraint and skill in their arrangement and selection must be exercised, however, if they do not merely detract from instead of leading the eye to and emphasising the figure.

The use or abuse of the accessory depends entirely upon the operator who uses it, and here we merely wish to talk about the object, not how it is to be introduced into a comparison. As we recently said, some of the objects we have chosen to class under the heading of this article might well have been considered with or as the background. These we will take first.

A door fixed into a wall used as a background and in such a position as to be suitably lighted and to be either included in the picture or left out of it, is an excellent aid to posing if used with discretion. Some charmingly natural positions will be readily suggested by it; the only danger being too frequent use.

The real windows of various picturesque designs that some photographers have been enabled to place in their studios are of great pictorial value. No one could possibly compare them with the painted imitations which have enjoyed such an unfortunate vogue. Were we building a new studio, we should have one of the ends panelled in dark oak of plain and simple design; this would provide a splendid ground for interiors, groups, or figure studies. In appropriate positions—presupposing, of course, that the architectural features of the studio allowed it—we should have a leaded glass window of obscured glass, and a handsome door, each of which would be sunk about six inches below the level of the surrounding panelling. When the whole wall was required without the window or the door, it would be a simple matter to place a facsimile piece of panelling over them made to fit flush with the remainder. It would be advisable that the door should open, but it need not necessarily lead anywhere; a piece of black velvet would be sufficient to give an idea of space beyond it.

Many portraitists will have natural features existing in their studios which, perhaps overlooked, will nevertheless be capable of pictorial use. Real stairs, the stair head, or a cupboard can generally be used for some exposure or another. If they have not been tried before, the photographer will be agreeably surprised at the lack of artificiality and unconventional appearance of the results. Perhaps articles of furniture are the most common accessories, but they do not necessarily give that touch of reality so valuable and convincing in photography. The objects sold ostensibly for studio use are in nearly every case abominable. Even the upholstery is of a shouting pattern, and as for design, the least said the better; it is generally as far removed from art as—well, the products of the "tintyper."

No furniture must be allowed under the skylight that savours in the least of anything but ordinary pieces; it

should be entirely appropriate and acceptable for an ordinary sitting-room. Some of the new style modern furniture is excellent, their straight lines and plain features once more emphasising the fact that simplicity has its own charm. Genuine Sheraton or Chippendale cannot, of course, be beaten; they give an impression of subdued but nevertheless comfortable gentility to any studio, and one also most useful for posing, or as mere accessories. It may be said that only the wealthy can afford these antiques, and therefore for some, or shall we say most, sitters, this furniture will be in bad taste, because inappropriate. This, however, we consider rather too particular, for although these old pieces always enhance the appearance of an interior, yet they are unobtrusive, and it is doubtful if more than one sitter in a hundred can name the style. Moreover, the value of the compliment implied by the use of these expensive accessories in a portrait photograph must not be forgotten. Again, modern furnishers supply examples of antique models which possess all the grace of line and form of the original specimens without the same careful personal craftsmanship which made these beautiful specimens of art applied to utilitarian uses so valuable. These are to be found in many middle-class homes, and the photographer might use them, too, so the question of appropriateness is of no great consequence.

Much of the early Victorian furniture was indisputably ugly, besides being too heavy and cumbersome for studio use. The later models of the era were very ungraceful and, with their wealth of turnings, obtrusive and calculated to give many high-lights. If one has a very fashionable clientèle something more ornate and blatantly expensive than the old English types may be used. The French styles of the last Louis's, for instance. There are many commercial interior grounds painted in the decorative style of the country and the age; with a sitter gowned in satins or silks very sumptuous effects can be obtained without overstepping the bounds of unity.

Small tables, which, of course, must be substantial and good, are alone useful in the operating room. A small oval one, as pointed out by the late H. P. Robinson, is particularly handy. If one turns to reproductions of Academy pictures, one will be surprised to note how frequently the brethren of the brush introduce small settees large enough for two. The photographer will notice how admirably they adapt themselves for graceful posing, either of ladies or groups. The uncommon one with arms and back in one wave, are particularly suitable. This reminds us that the old-fashioned settles are occasionally useful, providing as they do a seat, and with their high backs a background in one.

## THE P. P. A. EXHIBITION.

THE exhibition of photographs by members of the Professional Photographers' Association now being held at the house of the BRITISH JOURNAL OF PHOTOGRAPHY has already attracted many visitors, chiefly professional photographers in London and the provinces, and it is expected that many more will inspect the examples of portraiture before the exhibition closes on November 10. Among those who have already signified their interest in the aim of the BRITISH JOURNAL to promote an exchange of views between professional photographers are:—Frank Brown, Leicester; Martin Jacquette, London; Gordon Chase, Tunbridge Wells; H. A. Chapman, Swansea; H. C. Spink, Brighton; Herbert Allison, Armagh; A. Langfier, London; William Hollier, Dorking; Frank J. Hill, London; Edgar Scamell, London; H. Lang Sims, London; Francis T. Beeson, London; H. Christopher Hadley, Lincoln; William Gill, Colchester; Arthur Winter, Preston; Sydney H. Wood, Darlington; H. J. Comley, Stroud; and Alfred Ellis, London.

In reference to the coloured portrait (No. 23) shown by Mr. Gordon Chase, of Tunbridge Wells, that gentleman is good enough to address to us some particulars of the method employed by him, which we are glad to publish for the information of those inspecting the photograph. Mr. Chase writes:—"I should like to say that, though the picture I show is rather out of the usual groove, it is nevertheless taken from an ordinary order, and is a line I have been doing regularly for the last eighteen months. When I add they readily command 25s. per doz., not coloured, against 15s. same quantity on the ordinary commercial mount, it is a good argument against the present inclination to lower prices to make business.

"The tinting of paper by 'airbrush' or 'aerograph' is itself easily and rapidly to match any colour print or complementary tone, size, etc., and the method in my case has gone a long way towards solving the question as to what mount, size, colour, shape, etc., to order, and at a great saving in cost.

In sending us some further specimens of his work Mr. Chase says:—"In my opinion a present-day photographer, equipped with an aerograph, hot mounting machine, guillotine trim (about 21in. blade), and an 'Ingento' beveller plus his signature, is quite independent of any bought mounts for the best class work. The lever trimmer is also useful for gripping pictures when bevelling.

"The ordinary cartridge paper is cheap, colour most suitable for sepia, and has the great advantage of not being expensive bad stock. I am sure I am not the only photographer who at some time bought a lot of dead mounts, well chosen in estimation, that somehow nevertheless fail to take with clients, and ultimately get thrown aside.

"Another distinct advantage is the picture's position on the mount is decided for each subject, either right, left, or, if uncertain, the centre, whereas in the mounts bought with p.m. or fixed in one corner it generally happens to be the wrong one, or get the correct balance, and if used is decidedly faulty. My mounts are 'sepia,' but red chalk. 'Sea green' pictures with sepia tint and signature are equally effective, and I have generally found that one window filled with set of specimens all of one colour generally attracts better than mixing them. I therefore keep sets of different sizes in each colour for show.

## SOME PRESS OPINIONS OF THE EXHIBITION.

Organised by the Professional Photographers' Association, which is now in the fifth year of its existence, an exhibition was opened at 24, Wellington Street, Strand, yesterday, which should be of general interest to the profession. Each of the eighty exhibitors is a professional photographer, and only one print comes from each studio, of which it is considered an average production.

All the studies were originally made for sale to customers, so that both subject and execution have been restricted by commercial

requirements, but from this very reason a good opportunity afforded friendly rivals of appraising one another's normal workmanship. Most of the subjects come under the heading of portrait, and there are several striking examples of this art from different parts of the country.—"Tribune."

A novel little photographic exhibition was opened on Thursday 24, Wellington Street, Strand, admission to which is free, consisting of eighty prints, each of which is the work of a different man.

of the Professional Photographers' Association, the leading idea of the organiser, Mr. G. E. Brown, Editor of the *BRITISH JOURNAL OF PHOTOGRAPHY*, being to illustrate what are the prevailing types of "show-case" photography in the London and provincial studios. Amongst the exhibitors are to be found the names of Mendelssohn, Langtier, Jacolette, Fellows Wilson, Ellis and Walery, H. P. Robinson and Son, Spink, Percy Lankester, W. and D. Downey, and Harold Baker, with others of similar merit and distinction, from which it may be gathered that some interesting and profitable comparisons are available. Although there are several very fine examples of commercial portraiture on the walls, assuming that the collection as a whole represents what sitters approve, it indicates that the artistic requirements of the public are very easily satisfied.—"The Morning Post" (Mr. Hector McLean).

The exhibition which the Professional Photographers' Association is now holding at the house of the *BRITISH JOURNAL OF PHOTOGRAPHY* in Wellington Street is not an exhibition of special efforts to attain the uncommon in any way; but, in the words of an official, "just every-day work—what the exhibitors are doing daily for their cus-

tomers. All the same, the show is designed to let people, and the country visitor in particular, know what is going on in professional photography, and to elevate the status of the profession. Besides, we are trying to work up to giving certificates of competency to assistants, so that the public will know a good from a bad photographer."

The exhibits are almost entirely portraits. A high level of excellence is maintained throughout. Chief amongst the photographs for artistic beauty is that of a young girl in a carelessly thrown-on wrap, sent by Mr. Henry Spink, of Brighton. It is very delicately hand-coloured, and set in a mount which looks like the edge of a print stained with age. The whole treatment and appearance is a wonderful imitation of a bygone school of portraiture, adorned with every triumph of modern skill and the pose and look of the subject is perfect in its innocent childishness. Miss Caswall Smith has a striking study of a priestly face in a cowl. The features, the atmosphere, and the treatment are alike strong; it is a bold idea well carried out. Several other photographers have sent in fine work, the Elite Portrait Company having a most artistic study of a girl's head.—"Westminster Gazette."

## M. DEMACHY ON THE RAWLINS OIL PROCESS.

From "Camera Work."

The oil process is no novelty. It was invented by Poitevin at the same period as gum bichromate, in 1855, and revived by Mr. H. Rawlins, in 1904. A full description of the working of it is to be found in the October number of the "*Amateur Photographer*" (London) of that same year. The results were not all that could be desired. Since then Mr. Rawlins has amended and simplified his methods. A few months ago I took the process up a second time, in order to give a fairly practical account of its working conditions in a book that the Paris Photo-Club has just brought out, and I have come to the conclusion that oil printing has come to stay, and that it is an extremely valuable addition to the actual processes used by pictorial photographers. In fact, I know of no other method that can allow such freedom of treatment. But the process does not seem to have been specially studied from this point of view—the main point, in my opinion—and the experiments I have been making on different papers, with different inks and varied degrees of exposure, may interest those amongst my readers for whom values and quality of medium have some importance. On the contrary, from the "straight-print" point of view, the process will prove tedious, and quite inferior to platinum. This as a warning.

### "Oil" and Collotype.

Photographers are supposed to know that a thin layer of bichromated gelatine, when exposed to light, in contact with and under a glass negative, will shortly develop a brown image, which, once plentifully washed and then dabbed with blotting-paper, will show a faint relief, and a curious difference of surface between the exposed and protected portions. These last will be damp and shiny, the others matt and relatively dry. This is the first stage of the Rawlins process. At the next one, photography steps out; it has nothing whatever to do with the rest of the operations, which are as follows: If a layer of greasy, coloured ink is spread over the damp film, it will stick to the matt parts, and be expelled by the moist ones—a positive image will result. Not a crude black-and-white image, such as one would think probable, but one with the most delicate half-tones and the most perfect modelling. Spread the gelatine over a thick sheet of glass, and you will have a collotype plate; spread it over a sheet of paper and you will have a Rawlins print. It is simplicity itself.

Collotype printing is used all the world over, so it is but natural that Mr. Rawlins should have chosen at first the collotype inking method—with the roller. But his thin gelatine film spread over wet and spongy paper was often more or less abraded by the repeated passage of the rubber or leather cylinder. And the fatty ink, sinking through the disintegrated gelatine, stained the underlying paper, and spoilt the picture—spoilt it irretrievably. Moreover, the mechanical action of the roller suppressed all possibility of interpretation on the part of the worker. The only difference between the

Rawlins and the collotype processes, was that the Rawlins print was unique, and the collotype print numberless—both were impersonal. But since Mr. Rawlins has used stencilling brushes for inking, new horizons have opened. The picture may be inked locally, whole portions may be suppressed simply by non-inking, other portions darkened to any degree by repeated inking, and the layer of ink being extremely delicate, half-tones or high lights may be introduced at will by brushing the pigmented oil away.

Thus we find that the pictorial photographer has at his disposal a process which allows of absolute control over the values of his picture. He is now wholly responsible for their correctness, and can no longer argue that his negative gave it so, when some glaring fault of relation is pointed out to him. His negative will still be faulty—for he cannot yet exercise sufficient control over his lens and his plate—but his positive image may be true, and we sincerely hope that it will become so, for sins against values are so common amongst the fraternity that one has come to doubt if photographers know that they are there. We have given a résumé of the oil process; it is necessary to describe more fully the methods of Mr. Rawlins, and the modifications introduced by myself in the course of several months' experiments.

### Papers for the Oil Process.

Mr. Rawlins has had a special paper made for his process. It is a good and reliable paper, but up to now the firm that supplies it has not been able to meet the demands made in France, and we have been obliged, much against our will, to shift for ourselves. After a few unsuccessful trials, I have found a brand of double transfer paper somewhat different from that of Mr. Rawlins, but which works well, stands the strain perfectly, and gives results that I find satisfactory. The best samples are the numbers 100, 103, 118 (matt engraving), 118 shiny, and 125, of the carbon double transfer papers T.I.C. (Horseshoe), of English manufacture. Other double transfer papers may give as good or even better results. No. 100 is white, thin, matt, and smooth; 103 of the same style; 118 is made matt, slightly grained, and also shiny—the last cream-coloured; 125 is very thick, matt, and white. They are sold in rolls three metres long and 70 centimetres wide. The best way to avoid the nuisance of cutting out the sheets of necessary dimensions for use, is to saw the roller in a number of different sections of the requisite width. It is then easy to cut the length that is wanted off these reduced rolls, with a sharp penknife, using the roller itself as a guide or ruler.

### Accessories.

The stencilling brushes recommended by Mr. Rawlins are those that are used by painters on porcelain. They are made of bears' hair. Mr. Rawlins uses the same sort of brushes (with flat or nearly

flat surfaces) for inking and for dabbing. I have found that, for inking, the stenciling brushes of the same nature, but of different form, with the hairs mounted in the shape of a stag's foot, are immeasurably superior in delicacy and smoothness of action. They spread out fan-wise, and do not crush the pigment and gelatine together, as the straight ones do. They are made of all sizes, from one-third of an inch to an inch and a half wide. The largest size is most convenient for inking quickly and very slightly the whole surface of the gelatinised sheet. One brush of this kind is sufficient, but it is necessary to get several of intermediate size—half an inch, and two-thirds of an inch, and a few smaller ones—with two or three straight-cut brushes. A series of hogs'-hair oil brushes of different sizes, and a few sable brushes, will come handy for removing the colour in the high light. My first experiments were made with Mr. Rawlins' special ink—a thick, tacky sepia that works very well; but subsequent trials have convinced me that complete liberty of interpretation can only be reached by having at one's disposal several samples of ink of different thickness and composition. I have often found it necessary to use locally, on the same print, two or three different inks, of the same colour, but of various degrees of tackiness, according to the degree of stickiness of different portions of the gelatine relief. One must have actually seen the contradictory effects of two samples of different ink on the same print, to believe that such completely opposite results can be caused by a minute difference in the proportions between oil and pigment.

#### A Selection of Inks.

It is next to impossible to know the composition of the different inks on the market. Each maker has his own formulæ, and surrounds the mixing of his inks with the darkest mystery. I shall never forget the look on the foreman's face, at Valette's, on the Quai Montebello, when I asked him what a certain precious sample he was showing me was made of. The basis of engraving ink is boiled linseed oil, that is certain; but Lorilleux, Valette, Lefranc, and two or three other well-known makers, have their own trade secrets, and their respective inks do not give the same effects. I suppose it is the same thing in New York. Mr. Stieglitz, great expert in printing matters, will know. American workers in oils should experiment first with Mr. Rawlins' inks, then with four or five samples of engraving, lithographic, and common printing inks—with and without siccatives, and with and without thinning medium—and watch the results. The general rule is as follows: Thick, tacky ink causes contrast; fluid ink, such as ordinary oils, flatness. It follows that an over-exposed print will give a good image with thick ink, and no image at all with fluid ink, for it will ink all over—and vice versa, of course.

This is why I insist on the necessity of having different samples of ink handy for use on the same print, for it may happen—as it often does happen—that a false value, for which the negative is responsible, has to be toned down; in other words, that some portion of the picture has been, from an artists' point of view, under-exposed. It must be treated accordingly, and dabbed with fluid or extra-fluid ink, just as thick and tacky ink will have to be applied locally to portions that take too much pigment, and lose their modelling. Patient working with the same sort of ink chosen for the rest of the picture will not produce equivalent results, as experience has proven. For extreme cases, I can recommend a tube of ordinary oil colour and one of siccatives—to be used sparingly.

#### Sensitising.

I have quite abandoned Mr. Rawlins' method of sensitising (immersion in a 10 per cent. acid bath of potassium bichromate). The gelatine takes hours to dry; the paper, soaked right through with chromic solution, requires a long and thorough washing; and in summer the gelatine, unless the bath is cooled down with ice, will become dangerously soft. Instead of this I have adopted the following method:—

Make a stock solution of:

Water .....	100 cubic centimetres.
Ammonium bichromate .....	5 grammes.
Carbonate of soda .....	0.5 cubic centimetres.

For use, take 5 cubic centimetres of this solution, and add 10 cubic centimetres of alcohol of 90 degrees. Pin your gelatine paper on a sheet of thick blotter fixed to a drawing board, and brush the gelatine side of paper right and left with a two-inch wide flat brush of hogs'-

hair dipped in the alcoholic solution. Fifteen cubic centimetres will cover five whole-plate sheets. A few parallel lines may remain on the film just after sensitising, but they will disappear in the course of drying. Desiccation will be completed in fifteen minutes at the most, a formidable gain of time on the previous method. Also the gelatine having alone absorbed the sensitising solution, the elimination of the chromic salts will be much easier than when both gelatine and paper have been impregnated. After a few minutes' washing, the yellow tint of the bichromate will have disappeared, after which half an hour's soaking in cool water or five minutes in tepid water will be sufficient for the unexposed parts of the gelatine to absorb the necessary quantity of water. The print may be pigmented immediately, or hung up to dry, and inked at some later period. In this case it will require, of course, a preliminary soaking, rather more prolonged than the first one, for gelatine that has dried once will be tougher than usual.

Alcohol and ammonium bichromate sensitised papers print very quickly. A transparent negative of the kind that bromide workers would call thin, will not require more than two and a half minutes' exposure in diffused light on a bright summer's day—five or six minutes in winter. This for No. 100 double transfer Horseshoe paper, the coating of which is thin. No. 125 will require, for an opposite reason, double the exposure. But on no account must the opacities of the negative be printed through; in all cases no details, or only faint details, should appear in the high lights. A few intelligently conducted trials with the same negative will soon give one complete control over the printing operations, so much so that one will soon lose the habit of opening the printing frame to watch the results, a glance at the negative will be enough to judge beforehand the proper length of the exposure.

#### Methods of Manipulation.

We already know that the picture we are going to build up will be made by the difference of adhesion of fatty inks on swollen or retracted gelatine. Plain reasoning will demonstrate by simple deduction that the gelatine surface of our print must be damp, and that it must be kept so during the whole period of pigmentation, or it would take the ink on its whole surface; also that it must not be actually wet, because of the presence of even a very thin layer of water over the insoluble parts would destroy the difference of texture between them and the swollen portions of the film. These two important conditions may be fulfilled by gently pressing a sheet of fluid blotting-paper over the gelatine side of print, until every apparent drop of water has been sucked up, and by using as a desk on which the print will be placed during development, a thick pad of soaking wet blotting-paper supported by a sheet of strong glass, which we will prop up at a convenient angle on a support of some sort. This developing-desk or easel must be placed in the full light of a window, the light falling sideways on the print, so as to avoid disturbing reflections. The operator is comfortably seated, with his palettes on one side, and his brushes handy on the other. He will now choose his inks, according to the degree of exposure he has given, and to the effect he is striving after; bearing in mind that tacky ink will produce grain and contrast, fluid ink smoothness and flatness.

The ink may be taken up copiously at the end of the development when things are clear, and the general effect largely indicated, but the initial inking should be faint. So the ink that we will start with will have to be spread over the palette—a slab of porcelain ground glass, or ordinary glass—in a very thin and equal layer, always superior in diameter to that of the brush that is going to be used, or else the hairs will not be uniformly charged with pigment. Dab the stag's-foot stencilling brush five or six times over the thin layer of ink, and transfer the pigment to the print with rapid and light touches, holding the brush nearly perpendicular to the print, so that the wedge-shaped point, which must be kept uppermost, touches the print first, and opens out as you press downward. As to where you will begin your inking, that is a matter of personal taste. As a rule, a landscape may be inked all over faintly, and worked up locally afterwards; but for portraits I prefer to ink the face first—right up to what I intend to keep as a definite value, then I build up the surroundings to harmonise with the face value, taking great care never to introduce an accent as strong, or, worse even, stronger than those I have put in the face and figure. This

system has the advantage of showing clear, decisive work in the face, which is, of course, the centre of interest in a portrait.

For it is the same with the oil process as with water colours or oil, the best bit is the one that has been painted with a quick and sure touch. I do not believe in messing over a face, adding colour, and taking it away. I have done it, of course; but the result has never been equal to what I have accomplished with decisive and quick work. On the contrary, one may not hasten over backgrounds, for it is the value of the surroundings, and the localisation of the dark and light spots, that will make or mar a picture. It is the same in a landscape: after having very faintly developed the whole of the picture, choose your strongest spot, the one intended to catch and retain the eye, and work the rest up as a setting to that particular value; but do not dab haphazard all over your picture, or you will lose the thread of your argument, and end in pure drivel. Have you ever seen an expert ink a collotype plate? To the eye of the uninitiated the action of the roller appears to be identical when its passage adds colour or removes it. The experience of the beginner in oils is somewhat similar. The preliminary inking works quite smoothly, but after a time the brush seems to remove the pigment as fast as it is put on. Yet, after a few trials, one gets to recognise the feel of the springy motion that clears the spot, and of the lingering, insinuating touch that darkens it. Here is a rule that may be of use to the beginner: rapid and brusque action of the brush, be it perpendicular or horizontal, will remove colour from all slightly inked parts, and leave unchanged all parts more heavily covered; it will produce contrast.

### The "Hopping" Process.

The *hopping action*, described by Mr. Rawlins, is founded on this peculiarity. It consists in holding a straight-cut stencilling brush between the thumb and the two first fingers, perpendicularly to the print, which must then lie flat on the table, and in letting the brush fall on the pigmented surface, and bounce up again. It is caught as it bounces, and the movement is repeated over and over again. This is an excellent dodge for correcting any error in pigmenting—over-pigmenting, in fact; but I believe that it is wiser to try and get the proper result by inking progressively, than by forcibly removing pigment that has no right to be where it is. Experience will show that a picture with reserved whites looks infinitely better than one the whites of which have been produced by removal. But in the darker portions of the print, the use of the hopping action is often a necessity. There are half-tones, and also details in certain shadows, that it may not be possible to reserve. They will have to be inked over, and then picked out in the manner described above.

To resume, the result of my experiments in pigmenting seems to show that the less a print is worked upon, the better it will be. But, according to the scheme of tone adopted, the minimum of work may be five minutes in one case and an hour in another. What the worker in oils must bear in mind is that he has every advantage in trying to get his effect by the simplest means.

Mr. Rawlins mentions turpentine as the best solvent to use for removing the pigment down to the gelatine. I much prefer plain water. Absolutely white accents can be produced with a hog's-hair or sable brush (according to the thickness of the layer of pigment), dipped in cold or lukewarm water. And the action is thus limited to the actual portions that are submitted to friction—while turpentine or high-grade benzine will always dissolve more or less of the adjoining pigment, and, however, carefully dabbed away, will still change the normal thickness of the fresh pigment.

If you want to drive away every trace of pigment from the surface of your print, you can do it with a soft sponge, and cold, or slightly tepid, water, when the pigment has not been heavily applied; but in the case of a thickly-inked print, you will have to use automobile naphtha, which has the advantage of drying very quickly. Of course, the print should be soaked again before pigmenting, and it is safer to let it dry totally before soaking it anew, to avoid unequal swelling of the gelatine. Automobile naphtha will also come handy for the cleansing of the brushes, a messy, but all-important operation, which must be performed carefully and completely, before the ink collected on the hairs has had time to dry—at a safe distance from lamp or candle, of course.

Oil prints take a long time to harden, and even to dry, unless they are very slightly inked, and up to now I have not been able to make their surface scratch-proof. I have tried different kinds of varnish, but the really efficient ones show too much for my taste. The best results have been given by Soehnee's varnish for water colours, thinned down to one-third of its normal strength with alcohol of 90 degrees; even this is not entirely satisfactory. There is something to be done in that direction, as well as in several others, for though the process is not new, it has never yet been given a fair trial.

I sincerely hope that it will be taken up seriously by the American school of pictorialists, who will, I am sure, study it from one point of view only, and direct its evolution towards the proper goal. No photographic process exists that can serve as an apprenticeship to the Rawlins process. It is purely monochrome painting on somebody else's drawing—not photography—and the painter's rules must be followed implicitly, and with proper knowledge, or disaster will follow.

ROBERT DEMACHY.

## THE PHOTOGRAPHY OF FULL-LENGTH FIGURES.

From "Das Atelier."

ALTHOUGH the first effect we should strive for in photography is fidelity to nature, under certain conditions deviations therefrom are not only permissible, but even imperative, always assuming that the likeness to the sitter is not destroyed. Details may be altered to this end by retouching, but this is useless when it comes to altering the proportions of the human body. For this the negative must either be modified by optical means or a duplicate negative must be made in a similar way. Experienced photographers are all aware of the effect of printing figures and faces either in the direction of the length or breadth of the paper, according to which way the latter expanded.

Alterations of the proportions of the body during the exposure are only applicable when disproportions of the sitter are noticed before exposure. They are generally effected by causing the image to fall, not in the centre of the ground glass, but as near the edges as possible, so that the axis of the lens lies outside the image. This requires a flat field, such as shown by modern lenses. In this way it is possible to make a thin person look stouter, and also to lengthen or shorten the lower half of the figure in proportion to the upper. It is not possible to make a fat person look thinner or to shorten a figure without alteration of the fatness, or to obtain variations

in between. The possibility of thus altering the dimensions of the body on the original negative is therefore limited.

### 1. Turning the Axis of the Lens on a Horizontal Angle to the Line Between the Lens and the Sitter.

If we call the sitter  $M$ , the camera  $c$ , and the focussing screen  $m$ , Fig. 1, and shift the camera parallel to the focussing screen in the direction  $c'$ , the image will be at  $m'$ , and is broader than at  $m$ , and also differs, because there is another point of view. This is not the case if the image is shifted to  $c^1$  instead of  $c$ , Fig. 2, by merely turning the camera on a vertical axis, so that the position of the image is at  $c//$  and  $m''$ . In both cases the horizontal axis of revolution is  $\phi$ . The first process exactly corresponds to the reproduction of a person on the right or left side of a group taken with a wide angle—2  $\phi$  whereas in the second case the same angle is used, the position and lighting is the same as in a normal portrait, and is therefore preferable to the other. An example of both methods is shown in Figs. 5 and 3, whilst Fig. 4 is the normal position. The broadening in both cases is driven as far as possible with keeping the likeness, so as to show as much difference as possible. In practice one will hardly

ever go so far as this, unless a caricature is wanted, when, of course, the limits here laid down may be overstepped. It should be noted also that the broadening of face and figure is only noticeable when compared with the normal pose, and that a horizontal  $\phi$  has no effect on proportions of the height of the figure.

## 2. Raising or Lowering the Lens Axis.

It will be at once seen that this process—as will be seen from the angle  $\phi$ —corresponds to the second process described under 1, and

## Variations by Duplicate Negatives.

Alteration in the proportions of the body by making first a positive and then a duplicate negative has the advantage that it always has the normal negative for comparison, so that the amount of variation can be more accurately estimated, and also that the effects obtainable by the process described in the above section can be obtained to a much greater extent, and results even secured which are quite unattainable by that method, which range from

Fig. 4.

Fig. 5.

Fig. 6.

as Fig. 6 shows when compared with Fig. 2. Still the effect is strikingly different according to whether the lens is raised or lowered, as will be seen in Figs. 7, 8, and 9, in which Fig. 8 is the normal picture, Fig. 7 that taken with the lowered lens, and Fig. 9 that with the lens raised. In Fig. 8 all the proportions of the body, from top to toe, are normal, in Fig. 7 the upper part and head are considerably enlarged, so that the whole figure, although longer than Fig. 8, appears smaller and almost dwarf-like, whilst in Fig. 9

most delicate correction to the grossest caricature. Results may in fact, be obtained by photography which have hitherto only been attained by drawing.

The necessary modifications can be effected either when making the duplicate negative from the positive or when making the positive from the original negative, or with both. In the first case it is advisable to use the carbon process for making the positive, and the second both must be made in the camera.

Fig. 1.

Fig. 2.

although actually smaller than in Fig. 7, the sitter appears considerably taller and thinner than the others, because of the small head and long legs, and has a distinctly more aristocratic appearance than Fig. 8, to say nothing of Fig. 7. The nearer the head is to the lens axis and the further the feet are from it, is the more advantages for ordinary men in whom short legs are in the preponderance.

Fig. 3.

To obtain effects as described in Section 1, it is only necessary to place the transparency in the position of the sitter in Figs. 1 and 2, and it is best to place it head downwards; then on the focussing screen the action of the increase of the angle  $\phi$  can be most conveniently observed. To obtain a character a wide angle lens should be used, and if the half of this is  $= \phi$  and  $30^\circ$ , the head will be enlarged 1.5 times more than the feet.

### Enlarging or Reducing Certain Parts of the Figure.

This method is very similar to that used for remedying the distorted lines of a building, only it is the reverse. If in Fig. 10  $oo'$  is the original negative,  $c$  the lens with horizontal axis, and  $rr'$  the transparency, or  $oo'$  the transparency, and  $rr'$  the duplicate negative, the image at  $r$  is smaller than that at  $o$  and that at  $r'$  greater than that at  $o'$ . If the method is used to produce the transparency as well as the duplicate negative, the effect is doubled with equal

sufficiently reduced. In most cases it is advisable to make a carbon transparency and copy this, as one can then see, not only the shape, but the light and shade.

To broaden a thin figure it is only necessary to turn the focussing screen on its vertical axis.

### Combined Corrections.

When a normal transparency has been made it is easy to make one or more corrections in the camera. If the legs are too short the positive, which should be placed head downwards, should be tilted

Fig. 7.

Fig. 8.

Fig. 9.

inclination of the lens axis to the plate. As the inclination of the lens with small stops can be considerable, much greater caricatures may be made than by the method described above. For instance, with a 4 or 5 inch lens on a half-plate the ratio of the head to the body may be  $1\frac{1}{2}$  to  $2\frac{1}{2}$  to 1.

To make a stout figure thinner, a long focus lens should be used, if possible, and if the original negative is placed at double the distance from the lens with the head at the bottom, as for a normal copy, and then the negative be turned on its vertical axis till the figure is

forwards, whilst if the legs are too long it should be tilted backwards. If the figure is too stout then it should be turned on its vertical axis.

The two corrections may be made on the ground glass by swinging it in or out or sideways. Or the one correction may be made with the transparency and the other with the ground glass.

In all these corrections care should be taken that the figure does not fall too near the margins of the plate, otherwise it may be too easily seen.

F. STOLZE.

## SULPHITE SOLUTIONS THAT WILL KEEP.

From Eder's "Jahrbuch."

1903 MM. Lumière and Seyewetz described the physical causes of the decomposition or oxidation of solution of sodium sulphite. The purpose of this article is to draw attention to the chemical means which will so delay the oxidation of the usual 5 per cent. solution of sodium sulphite that for ordinary purposes this problem may be considered solved.

In 1898 there appeared an article in the "Zeitschrift f. Physikal. Chemie" (vol. 26, page 493), by S. L. Biegelow, entitled "Catalytic actions on the rapidity of the oxidation of sodium sulphite by the oxygen of the air." In this the author states that the oxidation of solutions of sodium sulphite by passing air through them is delayed when these solutions contain small quantities of benzaldehyde, isobutylalcohol, mannite, glycerine, phenol, potas-

sium tartrate, or sodium succinate. These substances act in the order given, that is to say, benzaldehyde acts the strongest.

Biegelow's experiments were repeated in a modified way by A. Titoff, and reported in the same journal (vol. 45, p. 641). Titoff did not use air for the oxidation of the sulphite solutions, but solutions of oxygen in water, and studied in a very thorough manner the slow action of mannite. Both authors come to the conclusion that it is absolutely necessary to use distilled water to dissolve the sodium sulphite. The purer the water, the slower the oxidation *ipso facto* of the sulphite.

This treatise of Titoff's directed my attention to this subject, which is photographically of considerable importance, and I decided to test these negative catalysers as regards their action on the usual photographic 5 per cent. solution. As a preliminary experiment, a 5 per cent. solution of crystallised sodium sulphite was made, and

to half of it 2 per cent. of mannite was added. Fourteen days later a test plate was exposed and cut in two. Two amidol developers were prepared with the two solutions, and the plate developed in these solutions. The developer containing mannite gave a normal negative, the other no trace of reduction.

In order to study more accurately the time of retardation of oxidation of the sulphite by mannite the following solution was prepared.

#### No. 1 Solution.

Distilled water .....	1,000 ccs.
Sodium sulphite cryst. ....	50 gms.
Mannite .....	20 gms.

This solution was kept in a corked bottle, and altered in three months, as shown in the following table:—

Date.	Sodium Sulphite, Cryst.
1904.	gms.
14/4 .....	40.95
21/4 .....	39.81
12/5 .....	36.97
19/5 .....	31.46
14/7 .....	12.23

In order to see what was the action of an increased quantity of mannite, a second solution was prepared only with 4 per cent of mannite. The following table shows its behaviour during five months:—

#### No. 2 Solution.

Date.	Sodium Sulphite, Cryst.
1904.	gms.
14/7 .....	30.95
16/8 .....	29.83
15/9 .....	27.32
14/10 .....	11.65
15/11 .....	6.00
14/12 .....	—

This solution contained, after five months, therefore, still 6 g. of sodium sulphite per litre. An amidol developer prepared with this gave, to my astonishment, a dense negative in five minutes.

Corresponding to 50 g. of the crystallised sulphite, 25 g. of the anhydrous salt, obtained from one of the first German makers, were dissolved in a litre of water with 40 g. of mannite. Many will wonder at the small quantity of sulphite used, but this was the quantity adopted.

The following table shows the behaviour of this solution in the course of six months:—

#### No. 3 Solution.

Date.	Sodium Sulphite, Anhydrous.
1904.	gms.
14/7 .....	17.135
16/8 .....	17.030
15/9 .....	16.570
14/10 .....	15.870
15/11 .....	12.690
14/12 .....	9.840
1905.	
17/1 .....	6.520

From the last two tables it will be seen that by the addition of 4 per cent. of mannite the ordinary sulphite solutions will keep for five or six months.

I thought it would be interesting to continue the experiments and to test the preservative properties for sulphite solutions of glycerine

An important change in the postcard trade is the resignation of Mr. F. T. Corkett, who has been studio manager and reproduction expert to Raphael Tuck and Sons, Ltd., for the last six years. Mr. Corkett took over the postcard section when it had very insignificant proportions to the present, and he has been with the business during its immense rise and present great success. Mr. Corkett has resigned, we have been informed, to start in business for himself, but at the time of going to press there is not, we understand, a definite decision on his part.

and isobutylalcohol. A solution was prepared according to following formula:—

Distilled water .....	1,000 ccs.
Sodium sulphite, anhydrous .....	39 gms.
Glycerine .....	50 gms.

The behaviour of this solution during three months is shown in following table:—

#### No. 4 Solution.

Date.	Sodium Sulphite, Anhydrous.
1904.	gms.
16/9 .....	24.40
23/9 .....	22.63
30/9 .....	20.79
7/10 .....	19.01
14/10 .....	17.93
21/10 .....	—
28/10 .....	15.58
4/11 .....	—
15/11 .....	11.35
14/12 .....	7.25

From this table it will be seen that the addition of 5 per cent glycerine will keep sulphite solutions for three months.

To test the preservative powers of isobutylalcohol two solutions were prepared:—

No. 5 solution contained 4 per cent of anhydrous sodium sulphite and 4 per cent. of isobutylalcohol.

No. 6 solution contained 4 per cent. of anhydrous sulphite 2 per cent. of isobutylalcohol.

The behaviour of these two solutions during three months shown by the following tables:—

#### Nos. 5 and 6 Solutions.

Date.	Sodium Sulphite, Anhydrous.
1904.	gms.
16/12 .....	22.71
1905.	
17/1 .....	19.39
17/2 .....	14.61
23/3 .....	11.18
	15.72
	9.84
	5.79

A comparison of this table with table No. 3 shows that man is superior to isobutylalcohol as a preservative.

Finally, the preservative power of mannite on a concentrated solution of sulphite was tested. No. 7 solution contained:—

Distilled water .....	1,000 ccs.
Sodium sulphite cryst. ....	250 gms.
Mannite .....	20 gms

In the course of three months this solution behaved as follows

#### No. 7 Solution.

Date.	Sodium Sulphite, Cryst.
1905.	gms.
23/4 .....	176.70
3/5 .....	176.70
11/5 .....	163.46
18/5 .....	161.10
13/8 .....	151.26

I am indebted to Herr Rudolf von Stern, chemist to the St. Paper Works, for the analyses.

Finally, I may mention that 2 per cent. of mannite has proved to be a good preservative for sulphate of iron solution, as with addition it will keep for about a week. W. WEISSENBERGER

THE Cricklewood Society has been re-formed, and commences session on October 24 at the Windmill Hotel, The Broadway, Cricklewood. Membership and further particulars can be had application to the Hon. Sec., Mr. Reginald J. Layman, 19, York Grove, Cricklewood, N.W.

THE Hackney Exhibition.—At the forthcoming exhibition there will be a class for stereoscopic slides. Entries will finally close on Saturday, October 27.

## THE TRAILL-TAYLOR LECTURER—1907.

EDWARD WALTER MAUNDER, F.R.A.S., who has been invited to deliver the ninth Trall-Taylor memorial lecture, under the auspices of the Royal Photographic Society, at the New Gallery, Regent Street, on Tuesday, October 23, has been for many years in close personal touch with the application of photography to scientific investigation. Entering the Royal Observatory at Greenwich, in 1873, he has been engaged in many branches of astronomical research, chiefly in the examination, both visual and photographic, of the sun's surface. For many years now he has been in charge of this department, which is entrusted with the duty of obtaining a complete record of the sun on as many days as possible, these photographs having subsequently to be carefully and minutely measured on a delicate micrometer.

Mr. Maunder was elected a Fellow of the Royal Astronomical

[Photography by Elliott & Fry.]

Professor E. Walter Maunder.

Society in 1875, and has taken an active part in the work of that institution, serving on the Council, and also as secretary and vice-president.

In 1890 he founded the British Astronomical Association, which has since taken a high position in the initiation of astronomical investigations, and done much to popularise the study throughout the country of this association; he served as president from 1894 to 1896.

Bearing on his solar work, he has visited many parts of the world for the purpose of observing the sun during these few precious moments when our luminary is totally eclipsed. In 1886 he went to the West Indies, Lapland in 1896, India in 1898, Algiers in 1900, Mauritius in 1901, and Labrador in 1905.

Naturally, in so long and varied an experience, he has published many interesting and instructive memoirs, and his two books, "The Royal Observatory, Greenwich," and "Astronomy Without a Telescope," are excellent examples of his clear and easy style of imparting knowledge to others.

Mr. Maunder's subject on Tuesday next is "Photography in the Work of Greenwich Observatory." We shall be glad to send a ticket to any applicant sending us his name and address.

## MR. J. T. SANDELL.—AN APPEAL.

THE letter from Mr. J. B. B. Wellington in our columns last week, appealing on behalf of Mr. J. T. Sandell, has brought, we are glad to say, a number of liberal responses, which will form a nucleus for a fund towards the relief of Mr. Sandell's distressing circumstance. We are glad to publish the following list of donors, and we trust that others will contribute any sums within their power towards the amelioration of Mr. Sandell's lot. Mr. T. K. Grant, of the Lumière N.A. Company, with Mr. Wellington, has interested himself in the fund, and donations may be sent to either of these gentlemen or to ourselves.

The following donations have been received by ourselves and passed on to Mr. J. B. B. Wellington:—

	£	s.	d.
W. J. W. ... ..	10	10	0
J. C. Warburg ... ..	1	1	0

## THE SOCIETY OF COLOUR PHOTOGRAPHERS.

In response to an invitation issued by Mr. H. J. Comley, of Stroud, Gloucester, a meeting was held on Tuesday evening last at the offices of THE BRITISH JOURNAL OF PHOTOGRAPHY to consider the formation of a society devoted to colour-photography. Those present included Edwin T. Butler, T. Bolas, E. J. Wall, Sidney L. Young, S. G. Yerbury, A. Macpherson, A. J. Newton, E. R. Grills, C. E. K. Mees, George E. Brown, Henry J. Comley, H. Snowden Ward, F. T. Hallyer, W. E. Dalden, S. G. Kimber, Charles B. Howdill, and Bertram T. Hewson. On the proposition of Mr. George E. Brown, seconded by Mr. E. J. Wall, Mr. Snowden Ward was voted to the chair. Mr. H. J. Comley read letters from various persons interested in colour photography, including Dr Grün, Dr. Hutchinson, Dr. Jumeaux, Mr. O. Pfenniger, and others. A telegram was read from Mr. Sanger-Shepherd regretting his inability to be present.

A brief discussion took place on the form which a society for colour-photography might take, in the course of which it was suggested that the members might circulate an experience book with specimens, appoint a committee of advanced workers who would advise those in difficulties, and hold an annual meeting and exhibition. A subscription of 10s. was proposed, but an amendment placing the sum at 5s. was carried. Mr. H. J. Comley was elected secretary and treasurer, and a committee was also elected

to draw up a circular stating the objects and methods of the society. This committee consists of Messrs. E. J. Wall, Geo. E. Brown, F. T. Hollyer, and A. J. Newton, with the secretary.

## Photo-Mechanical Notes.

### Etching Machines.

We are hearing a good deal lately about etching machines. Such machines are required if they can perform the work as well and quicker than it is already being done, and especially if they can do it both quicker and better, a claim which has always been made for the Levy acid blast, and supported by comparative photo-micrographs which show the machine-etched plate to be both smoother and deeper than those etched in the tub as usual. Although we have read of this machine for so long, and it has been promised in England, we have not yet been privileged to see it. From an article in a recent number of the American "Engraver and Electrotyper," the Levy machine does not appear to be always an unqualified success, and reference is made to the introduction of another machine, the "Thorpe," which is being placed on the market by the Ostrander Seymour Company. This machine is arranged to rain the acid down on the plate placed face upwards, in contrast to the Levy, which blasts it up on the plate placed face downwards. It is also stated that a third invention is announced in America as being almost ready.

In Europe we have the Holmström etching machine, marketed by Messrs. Klimsch and Co., but this we do not think has yet been introduced into England. It consists of a large box, having the bottom pitched out or made of porcelain, holding the acid solution, in which one or two paddle wheels, driven by a motor, revolve rapidly, sending a spray of acid solution against the plate, which is placed face downwards under the lid of the box. It is said to be very successful; some of the results shown look excellent. Similar in principle is the Mark Smith etching machine, shown at the recent exhibition at the Agricultural Hall by Messrs. Hunters, Ltd. This is a porcelain box or kind of deep sink containing the acid solution at the bottom. In this an aluminium paddle, something like the screw propeller of a steamer, is revolved rapidly by means of a motor, and this drives the acid against the plate, held face downwards. We have no doubt this will etch deeper and smoother than any hand-etched plate in the same time with the same strength of acid, and an etching machine is only of service in so far as it does this.

Another machine that is to be seen in England is that invented by Dr. Albert. This consists of the ordinary etching tub placed on a stand. Over this is placed a cover, and inside the cover there is a frame to which is fixed a number of blades of aluminium, forming a sort of comb. This frame is fastened to an eccentric, which can be moved by turning a handle. The effect of this is to work the blades to and fro just above the plate, placed face upwards, in the etching solution. It is stated that this introduces air, which is necessary to the etching fluid used by Dr. Albert, the said fluid being made from a secret powder, sold to purchasers of the machine. The principle does not seem so good as that of the machines throwing a spray, nor do the results seem to our mind at all superior to hand-etched plates, either in depth or smoothness. As to speed of etching, we think that violent agitation of ordinary nitric acid solution by brush or other means would etch just as quickly and with the same want of depth and smoothness. The two latter machines are the only two on the market here, and when it is stated that the English machine costs £50 with a motor, while the German one costs £125 without, the latter being worked by hand, it will be seen that in this instance at least the process engraver can easily afford to be patriotic.

### The Royle Catalogue.

Messrs. John Royle and Sons, of Paterson, New Jersey, send us their latest descriptive catalogue of the Royle-Richards ruling machine. Though primarily designed for ruling wood-cuts, in which work, as the Royle catalogue shows, it is capable of superlatively fine results, it may be employed for ruling backgrounds in half-tone cuts, and should be found of great and useful application in the finishing and embellishment of half-tone plates generally.

Photo-engravers may also consider the feasibility of purchasing the machine for the commercial production of wood-cuts, the advantages of which, when finely executed, are, of course, well known to publishers of trade catalogues, etc., and are in evidence to perfection in the list of Messrs. Royle.

### Enamel Blistering Off

A querist of Messrs. Penrose's "Process Work," states his difficulties with the enamel process as follows:—

What is the reason for the enamel blistering up from off the zinc plate while etching? After burning in the zinc the enamel will not bear touching with a graver or anything to rule or touch up; it will splinter off the enamel. I have tried the enamel both thick and thin. The formula I use is:—Clarified glue, 2 oz.; albumen of one egg; bich. ammonia, 80 grs.; water, 3 oz. The fish glue we get from Messrs. Penrose and Co., and this formula we have used for a very long time. Is it the glue? There seems no body in the enamel when burned in. I should be very much obliged if you could help me either with another formula or say what is the matter with what I am using. We have had to discard the enamel for a time.

In reply to which a reader, Mr. S. Scholes, advises the use of the following formula:—

Fish glue reclarified.....	5 ozs.
White of 1 egg .....	
Amm. bichromate.....	120 grs.
Chromic acid.....	5 grs.
Water .....	5 ozs.
To reclarify fish glue take:—	
Fish glue.....	20 ozs.
White of 4 eggs .....	
Water .....	20 ozs.

Mix thoroughly with an egg beater and then put on gas, letting it boil for about three minutes, watching it very carefully to see that it does not boil over, then filter through a flannel jelly bag while hot; allow this to get quite cold and mix up the fish glue as follows:—Add the fish glue, eggs, and half the water together, mix thoroughly, then dissolve the bichromate and chromic acid in the remainder of water, and add this to the fish glue, slowly stirring all the time. Allow the solution to settle, filter well, and it is ready for use. Clean the zinc plate and put into:—

Nitric acid.....	$\frac{1}{2}$ oz.
Alum .....	2 ozs.
Water .....	20 ozs.

for about one minute, place under tap and rub with a piece of cotton wool; this will give the plate a matt surface and will help the film to hold on better; coat the plate in the ordinary way, and whirl dry over a gas. The film should be kept as thick as possible. Put the plate out to print and carry same through, drying it and developing quite clean; now before dyeing it you must put it into a hardening bath which has been made up 48 hours, and put into daylight to ripen:—

Amm. bichromate.....	1 oz.
Chromic acid.....	80 grs.
Methylated spirit.....	2 ozs.
Water .....	17 ozs.

Leave the plate in this for three to five minutes and dry in strong light; when dry it must be cooked up with a very powerful gas burner as quickly as possible, using a grid-iron for it, as the zinc plate is so likely to bend and melt when finished. Put on slab to cool, then etch in the ordinary way. There is nothing wrong with the fish glue, and the reason there is no body in the glue is (1st) twirling too fast, (2nd) cooking up too slowly.

### The Zander Four-Colour Process.

In reference to the recent criticism of Baron von Hübl, Mr. Zander sends us a reproduction of shaped hats, stating that the same is for inspection. This, with other specimens sent, is stated to be "a rough pull from unfinished blocks" by his four-colour process, and it is claimed that such results could not be obtained by three-colour. We are afraid we cannot make this admission, as we have seen plenty of three-colour proofs of equal merit. In any case, this is not a fair example, as few of the hats show the whole of the four-colours printed on them, some of the work being either deep, etched away, or engraved away by hand. This would therefore take more time than ordinary three-colour, and depends upon extremely skilled labour, having very little or nothing

to do with the particular method suggested by Mr. Zander, which, if it is any improvement at all, must justify itself by its mechanical superiority. If work is to be finished by hand to such an extent, it would be better to use special colour-filters and special inks appropriate to the particular subjects to be reproduced. We should like to see some subject reproduced by Mr. Zander's method, in which no work has been cut away, or, better still, without any fine etching at all.

#### PHOTO-MECHANICAL PATENTS.

**ETCHING PLATES.**—No. 20,321. Improved method of etching and apparatus for the production of half-tone, line, and other process printing plates. Harry Guy Bartholomew and Herbert Moir Bussy, 149, Strand, London, W.C.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received from October 1 to October 6:—

**EXHIBITING POSTCARDS.**—No. 21,616. Means for exhibiting picture postcards, and the like. Alfred William Zallop, 14A, King Street, Great Yarmouth.

**IMPROVED MATERIAL.**—No. 21,698. Improved material on which photographers and artists can produce pictures. William Buist Picken, 35, Agamemnon Road, West Hampstead, London.

**STEREOSCOPES, ETC.**—No. 21,743. Improvements in stereoscopes, projection lanterns, and the like. Kingsway Syndicate, Ltd., and William Mountstevens Gillard, 7, Southampton Buildings, London.

**DISPLAYING PHOTOGRAPHS.**—No. 21,842. Improvements in and relating to holders for displaying photographs, picture cards, and the like. George Hayes, 36, Chancery Lane, London.

**FOCAL PLANE SHUTTERS.**—No. 21,877. Improvements in or relating to focal plane and other roller blind and shutters for photographic purposes. Arthur Lewis Adams and Walter George Roberts, Birkbeck Bank Chambers, Chancery Lane, London.

**DAYLIGHT LOADING CAMERA.**—No. 21,881. Daylight plate loading and reloading box camera. Phillip Anton Schmaus, 6, Romilly Street, Liverpool.

**PLATES, ETC.**—No. 21,975. Improvements in apparatus in which photographic articles are treated in liquid. William Laurence Parkinson, 15, Walter Street, Liverpool.

**CAMERAS.**—No. 21,981. Improvement in photographic cameras. Charles Howdell and George Lloyd Moore, trading as the Midland Camera Company, Ltd., Slaney Street, Birmingham.

**ROLL FILM HOLDER.**—No. 22,087. Photographic roll film holder. Arthur Mason, 63, Shepherd's Lane, Leeds.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**SHUTTER.**—No. 21,950. 1905. This invention is for a shutter or screen for exposing a plate in sections, one or more at a time. A strip of opaque cloth or other opaque flexible material is divided into sections by lines drawn across it. Any number of sections may be used of the same size or length, and they are suitably perforated with one or more holes of suitable shape and size, and registered in position so that when an exposure of the plate has been made with each section separately, the whole of the plate will have been exposed. The end of the strip of opaque cloth, paper, or other flexible material is fastened by a hook or any other means to rollers, and the strip wound thereon, the rollers being furnished with a flange at either end

to ensure the strip rolling evenly thereon. The other end of the strip is then fastened to the other roller, enabling it to be wound from one roller to the other. An indicator is fixed to the rigid frame, or may form a part thereof, to enable the sections of the strip to be registered in position, by bringing the dividing lines into alignment with the same while winding the strip from one roller to the other. The distance between the rollers affords room for only section of flexible strip to be in use at a time, the other sections being wound on one or other of the rollers. If the sections are correctly registered in position and all of them used one after the other, the perforations in the same will be so placed and be of such a shape and size, that the whole of the photographic plate or film will have been exposed. The position of the device in regard to the camera should be out of the plane of focus of the lens, so that the edges of the perforations will not be clearly defined on the photographic plate or film. The claims are: 1. A device for enabling photographic plates and the like to be exposed in sections constructed substantially as described. 2. A device for attachment to or insertion in a camera, comprising a frame provided with two rollers, such rollers having a band attached thereto, such band being provided with perforations arranged in such a way that as the band is moved intermittently from one roller to the other all portions of a plate or film may be exposed as required for the purposes set forth. The combination with a camera of a band or screen provided with perforations so formed that all portions of the plate or film may be exposed in divisions intermittently as required, without any portion being doubly exposed. 4. In a device for enabling photographic plates and the like to be exposed in sections. William Boyd Henderson, 108, Westbourne Grove, London, W.

**CATALYTIC PRINTING.**—No. 7,935. 1906. This invention is for an improved process for reproducing pictures by imprinting an original that has been treated with hydrogen peroxide. The catalytic method of multiplying pictures, as in Specifications No. 22,841, 1901, and 13,920, 1903, required the subsequent treatment of the impressed paper with a bath, but in this invention the paper or other surface is itself prepared in such a manner that the hydrogen peroxide produces the colour at once. The advantages are greater simplicity in working and the possibility of obtaining different effect, such as soft or hard prints, by varying the concentration of the solutions. Substances suitable for preparing such papers are manganous salts. Paper impregnated with one of these, after it has been pressed against the original picture treated with hydrogen peroxide, may be developed by ammonia, either alone or mixed with an ammonium salt. The following examples illustrate the process:—

No. 1.—Gelatine paper is impregnated with a solution of a manganous salt of 5 per cent. strength and allowed to dry. The invisible reproduction obtained on such paper is developed with a mixture of 20 c.c. of saturated aqueous solution of ammonia and 100 c.c. of water, or with a mixture of 20 c.c. of saturated aqueous solution of ammonia and 80 c.c. of a saturated solution of ammonium chloride.

No. 2.—A solution made by mixing 200 c.c. of a solution of gelatine of 20 per cent. strength, 20 grams of crystallised manganous chloride, and 200 c.c. of water is poured upon paper, glass, films or the like, and the surface is allowed to dry. The development may be as described in Example 1.

No. 3.—A mixture of 100 c.c. of a solution of gelatine of 20 per cent. strength and 250 c.c. of a solution of borax of 10 per cent. strength mixed with 100 c.c. of a solution of gelatine of 20 per cent. strength and 50 c.c. of a solution of manganous chloride of 25 per cent. strength is poured upon paper. The development may be as described in Example 1. Still more simple is the multiplying process when the paper or the like contains a substance which reacts directly with hydrogen peroxide without further treatment. Thus, cobaltous salts are oxidised by hydrogen peroxide, so that if a surface previously impregnated with such a salt at suitable concentration, be pressed against the original picture treated with hydrogen peroxide, a visible reproduction is produced without necessity for any development. These salts are not sensitive to the action of air, differing in this respect from the ferro-ammonium sulphate

previously used; indeed, they remain unchanged for any time that is likely to come into consideration in practice. An addition of an alkali salt of a feeble acid to the cobaltous salt is advantageous for the strength of the picture. This part of the invention is illustrated by the following examples:—

No. 4.—Gelatine paper is impregnated with a solution of cobaltous acetate of 10 per cent. strength. The paper thus prepared can be used, even long after it has been made, for copying a picture by the catalytic process by pressing the catalytic original that has been treated with hydrogen peroxide, against the paper whereby a visible reproduction is produced directly. If desired this reproduction can be intensified by treatment with solution of ammonia or of caustic soda or some other bath containing hydroxyl-ions.

No. 5.—6 grams of cobaltous acetate are dissolved in 100 c.c. of a solution of gelatine of 10 per cent. strength, and paper, glass, or the like is coated with the solution.

No. 6.—9 grams of cobaltous sulphate and 10 grams of sodium acetate are dissolved in 100 c.c. of a solution of gelatine of 10 per cent. strength, and paper, glass, or the like, is coated with the solution.

No. 7.—8 grams of cobaltous chloride and 10 grams of sodium salicylate are dissolved in 100 c.c. of a solution of gelatine of 10 per cent. strength, and paper, glass, or the like is coated with the solution.

No. 8.—9 grams of cobaltous acetate and 9 grams of sodium acetate are dissolved in 100 c.c. of a solution of gelatine of 10 per cent. strength, and paper, glass, or the like is coated with the solution.

No. 9.—8 grams of cobaltous sulphate and 10 grams of sodium ortho-nitrobenzoate are dissolved in 100 c.c. of a solution of gelatine of 10 per cent. strength, and paper, glass, or the like, is coated with the solution.

No. 10.—A solution of 8 grams of cobaltous acetate in 50 c.c. of a solution of gelatine of 10 per cent. strength is mixed with a solution of 7 grams of borax in 100 c.c. of gelatine of 10 per cent. strength, and paper, glass, or the like, is coated with the mixture. Gum-printing paper and pigment paper may also be prepared by this process by adding to the mixture of gum or gelatine and colouring matter the selected salt, such as cobaltous acetate or another cobaltous salt, or a mixture of a cobaltous salt, with an alkali salt of a feeble acid. By the action of the hydrogen peroxide the gum or the gelatine is made insoluble in warm water.

No. 11.—4 grams of cobaltous acetate are dissolved in 100 c.c. of a solution of gelatine of 10 per cent. strength, which contains a suitable colouring matter, and paper or the like is coated with the solution. Neue Photographische Gesellschaft, 27, Siemenstrasse, Steglitz, Berlin.

**PHOTOGRAPHIC PRINTING APPARATUS.**—No. 9,764, 1906. The present invention has reference to copying apparatus of the kind in which the negative and the sensitised printing paper are pressed against a rotatable hollow transparent cylinder, suitably illuminated, and refers more particularly to improvements in devices of this kind, as described in the prior Specifications 1753/05 and 1757/05, in which is described a copying apparatus comprising a hollow, transparent, illuminated cylinder mounted on a spindle, the negative and the sensitised printing paper being pressed into close contact with said cylinder by means of a number of narrow bands. Vastly superior results are obtained by employing in place of a number of narrow bands an undivided cloth, extending approximately the whole width of the cylinder, and in suspending said cylinder freely in the undivided cloth or band; the present invention therefore consists of a copying apparatus of the kind above referred to in which the transparent hollow illuminated cylinder around which the negative and the sensitised printing paper are passed, is freely suspended in a loop of an endless undivided cloth or band, whereby more perfect contact between the negative and the printing paper is obtained, and the various defects existing in apparatus of this kind as heretofore constructed are obviated. The claim is: In copying apparatus of this kind described, the provision of an endless undivided band or cloth, in which the

hollow transparent illuminated cylinder is freely suspended, hung substantially, as described, for the purposes specified. Hans Viggo, Siim-Jensen, Blegdams Hospital, 1, Blegdams Copenhagen, Denmark.

The following complete specification, etc., open to public inspection before acceptance under the Patents Act, 1901:—

**SCREEN PHOTOGRAPHY.**—No. 11,975. Whole-tone or line, and half-tone or screen photography. Mertens.

## New Books.

**"The Complete Photographer."** By R. Child Bayley. London: Methuen and Co. 10s. 6d.

This popular treatise on photography makes the fourth of a series of volumes, devoted to outdoor sport. We trust that no degradation of photography in the eyes of such of its stalwarts as the critic of the "Globe" will follow from its association under Messrs. Methuen's auspices with golf and motoring. The author, in his preface, rather conspicuously avoids a reference to the companion of his volume, the *raison d'être* of which, he tells us, is dilated upon the application of the endless "photographic formulae" to various enjoyable branches of photography. The sporting side of photography gets no kind of showing at all, save some reference to Mr. Mortimer's big-wave photography, and a reproduction of Douglas English's "Harvest Mouse," the latter representing but tepid form of sport after all. The goal of the serious reader of volume, so we assume, is the pleasurable sensation of success in photography—with aims at artistic expressions suggested as a mountain peak in the background, to which the clever photographer may at last attain. To the task of acquainting the reader with the details of present-day photography the author applies himself on a thorough system and with much lucidity. The first chapter is a sketch of the history of photography, and then we enter upon systematic course of instruction in the functions of apparatus, photographic optics, the fitting of the dark-room, exposure, development and its after processes, and the details of the various printing processes. Lantern-slide making and enlarging have a chapter to themselves, and orthochromatic and colour photography are treated together. Lastly come landscape, architectural photography, portraiture, and a chapter on "pictorial photography," of historical interest only, and noticeable for the omission of any mention of Horsley Hinton from a sketch of the rise of the British pictorial work. One may or may not think well of Mr. Hinton's influence on so-called pictorial photography, but historically he is a fact. The 410 pages of "The Complete Photographer" interests us all as recording what kind of photography is practised at the opening of the twentieth century. There is nothing in it that has not been said before; but, on the other hand, there is perhaps no one volume which so adequately treats of the many branches of photography practised by the amateur. The text pages are relieved by fine plate reproductions of photographs by leading pictorialists, among whom are George Davison, Craig Annan, Puyo, Demachy, E. Holding, Walter Benington, Percy Lewis, W. T. Greathouse, David Blount, Alfred Steglitz, Fredk. H. Evans, and W. R. B. The frontispiece, in photogravure, is Mr. Crookes's magnificent portrait of Irving.

A manual of "Lantern-Slide Making and Exhibiting" reaches us as No. 4 of the "Focus" series. The author, Mr. John A. Horsley, F.R.P.S., has done his best in the space at his disposal, and the volume contains a large number of hints expressed without the usual flow of words. The price is 6d.

**"Photographic Lenses."**—A new edition of this popular treatise on photographic optics has been issued by Messrs. R. and J. Limited, 68, Cornhill, London, E.C. The text has been revised and added to in many respects, which work, we presume, must be credited to the surviving author, Mr. Conrad Beck. For its lucid treatment of the elements of photographic optics the volume has our warmest approval. We especially admire the ingenious diagrammatic illustrations, of which the authors have liberally used in their exposition. The present edition makes good the omission of an index from the book as first issued.

New Apparatus, &c.

the Primus Clamping Table. Sold by W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.

The above accessory is offered as a remedy for the slipping of the print whilst being trimmed with a circular trimmer. It consists, as will be seen, of a framework provided with two sliding bars, which

hold the print and circular shape firmly in position. The apparatus achieves its object very satisfactorily, and certainly removes a source of failure in making circular prints.

New Materials.

Interior Bromide Paper and Postcards. Manufactured by the Birmingham Photographic Company, Stechford, Birmingham.

These papers have been lately improved, and the samples submitted to us are quite satisfactory, not only as regards surface, but also particularly as to colour and gradation, the latter having a range sufficient for every possible class of negative. Testing the papers on an actinometer of graded densities, from bare glass to a D. density of 3.01 or opacities from 1 to 1024, we find the whole range recorded. When one considers that the density in primary work is at the utmost about 2 it will be seen at once that the scale is very long and suitable for all classes of work.

The developer specially recommended is amidol, but using a normal metol-hydroquinone, the colour is a good rich black, without any tendency to rusty or greenish tones.

The developer specially recommended is amidol, but using a normal metol-hydroquinone, the colour is a good rich black, without any tendency to rusty or greenish tones.

Messrs. Houghtons have brought out a neat *passee-partout* mount for small prints such as the enlargements from the negatives made in the "Tikka" camera. The whole mount measures 9 by 7, and will take five prints, cut-outs being provided of different shapes. The mount is a welcome departure from existing patterns, and we shall not be surprised to learn that, at the price of 9d., dealers do well with it.

Mr. GRAYSTONE BIRD, 38, Milsom Street, Bath, whose lantern slides we have had the pleasure of commending for years past, sends us his list for the season 1906-7. It includes a large number of men, child, and genre subjects, cloud and sea studies, in addition to the North Wales series, and a number of illustrated hymns, the textual portions of which are from Mr. Bird's own negatives, and excellently illustrate and emphasise the words of the hymn. In technical qualities and artistic treatment of the subject the slides are excellent.

CATALOGUES AND TRADE NOTICES.

The Altrincham Rubber Company, Mossburn Buildings, Altrincham, have issued a price list of their various specialities in the English language. They have also issued a circular of testimonials in English, French, German, and Spanish. Either will be sent post free to any address.

Messrs. SALMON AND SON, 52, Mattock Lane, Ealing, London, W., send us their latest price-list for enlargements in black and white and colours. Messrs. Salmon issue a variety of attractive styles.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Ordinary meeting, October 11, Mr. A. E. Smith in the chair. Mr. Ernest Human showed prints made on "Platinchrom" paper, and said that the paper was of a platinum base, which was developed by the aid of steam. If the paper was allowed to get damp, one had the advantage that it printed out, and then only required clearing, which might be done either in a bath of common salt or hydrochloric acid. A further advantage was claimed for it, inasmuch as sepia, brown, red chalk, and blue tones could be obtained by the aid of special baths. At the same time, he must admit that he did not care for the blue, it being too like the old ferro-prussiate print, but the other colours named were exceedingly fine. Mr. A. Haddon gave "A Scientific Chat," which was highly interesting, inasmuch as it showed how science depended largely upon photography for recording its progress. The lecturer said his notes for the subject were largely the result of being asked to help a colleague in photographing streams of dye in conjunction with glycerine, and his trouble was to get a dye that was sufficiently opaque for photography. After some experiments he found that rose bengal, plus glycerine, plus another dye, plus Indian ink gave what was required. Special apparatus was made to show the induction of the "line of force," and in order to show what was meant by the line of force, Mr. Haddon showed various experiments by the aid of a magnetic needle and a series of magnets, showing how the two ends of a magnet repelled or drew the needle to it, whilst upon silver or copper the magnet had no effect. The address throughout was full of experiments, and was fully illustrated by the aid of prints showing the lines of force obtained by the aid of the dyed glycerine. A hearty vote of thanks to Mr. Haddon was proposed by Mr. Teape and duly carried. Mr. Haddon suitably responded. On Thursday, the 18th, Mr. T. E. Freshwater is to read a paper on "Photographic Notes," and on the 25th Mr. J. T. French will lecture upon "Here and There in Great Britain."

CROYDON CAMERA CLUB.—Mr. F. W. Hicks, on the 10th inst., gave a demonstration on "enlarged negatives," in the making of which he is an adept. All the advice given was, therefore, sound

and to the point. The lecturer laid stress on the importance of first obtaining a good transparency; either a slow ordinary plate might be used or a carbon positive, made by contact. In either case it should be fairly thin and soft, without clear glass or dense shadows. A slight spreading action occasionally appeared with carbon, which was undesirable. For the dry-plate transparency he preferred metal as a developer. In the production of the enlarged negative he advocated daylight as affording the best results, despite its tendency to vary, the correct exposure being ascertained in the usual way by successive exposures on a smaller plate of the same batch. A pyro-soda developer was employed, having a Watkin's factor of twelve, but he generally found reducing this number to eight gave him what he wanted; the factor number taken would, of course, depend upon the printing process for which the negative was intended. Mr. Hicks then proceeded to make a transparency, and by means of the club lantern a capital 12 by 10 negative was produced. Focussing was effected on a piece of white card of the same size and about the same thickness as the plate, pins being arranged as stops to ensure the dry-plate subsequently registering.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—On Monday evening, the 15th inst., Mr. E. Seymour lectured before the above society on "Flower Photography." In the course of his remarks he said that simplicity of treatment was the key to success. For background use a drawing-board faced with a sheet of picture-frame makers' cardboard either white, green, or brown in colour, according to the subject. Small flowers should be wired right up the stem; they may then be pinned to the background and gracefully posed without any fear of their shifting. Exposures must be full, and development should be for the high lights. Orthochromatic plates should be employed, but in very few cases indeed is a screen necessary. Print in bromide platinum or carbon. Green carbon is suitable for studies of leaves and grasses. Prints should be made direct from the negative, and not enlarged, as in the latter case a certain amount of fine texture and detail is sure to be lost. Special apparatus or special lighting facilities are quite unnecessary to secure even the finest results.

**SOUTHAMPTON CAMERA CLUB.**—Mr. C. B. Howdill, A.R.I.B.A., of Leeds, paid a very welcome visit to the above on the 15th inst., for the purpose of delivering his illustrated lecture on "Corsica, the Isle of Unrest," and a large attendance of members enjoyed themselves to the full. Round an excellent exhibition of some 150 slides the lecturer wove a tale of travel and adventure, which not only carried his audience with him, but showed the great powers of observation and illustration which he possessed.

## Commercial & Legal Intelligence.

The firm of Friedrich Schneider Nachfolger, mount-makers, of Berlin (46, Gitschingstrasse), has been taken over by C. Bandlow and M. Tragbar, who will carry it on under the title, Friedrich Schneider Nachfolger, Bandlow, and Tragbar.

**DEFALCATION by a Secretary.**—Before Mr. Alderman Burnett, at the Guildhall, last week, A. Ernest Trow, of Newquay, Lathom Road, Twickenham, attended on a summons, charging him with having, in April last, unlawfully, and with intent to defraud, made certain omissions from the "cash received" book of his employers—the Rapid Photo Printing Company, Limited, Bridgewater Square. Mr. S. Myers, who appeared for the prosecution, said the defendant was appointed secretary to this company in 1902, and his salary, at the time of his dismissal in September, was £300 a year. When the books were audited recently it was found that he had been in the habit of cashing cheques that should have been paid into the bank, and putting the money into his own pocket. With regard to a sum of £26 7s. 6d., it would be shown that accused received a crossed cheque for that amount from a customer. He called on the customer, and, telling him he wanted cash at once in order to pay wages, induced him to give an open cheque. This he endorsed, and never accounted for. The proposal was to prove one embezzlement, and, should the defendant plead guilty, to withdraw the charge of falsification. Evidence was given showing that defendant's defalcations

since April last amounted to £236. Accused pleaded guilty to embezzlement, and said he had had a considerable amount of trouble lately. The Alderman: It is my duty to sentence you six months' imprisonment, with hard labour.

**CHARGE against Canvassers.**—Charles Burstein, George bottom, and Alfred Burstein, all described as photographers, charged, at the Spelthorne Petty Sessions, with loitering in Coles Road, Hampton Road, and Anlaby Road, Teddington, at 10.40 a.m. on October 5, supposed for the purpose of committing a felony. Detective Magner said that shortly after 9 o'clock on Friday morning his attention was called to the prisoners in Clarence Road. He watched them for some time and saw one go into several houses while the other two remained on the footway. The last house they entered was The Chestnuts, which was unoccupied. They afterwards went into Queen's Road by North Lane. He followed them into Coleshill Road, where they did the same thing, and then went into Stanley Road. In Anlaby Road and Hampton Road they went to three houses, but did not ring the door-bell. He found they had spoken to a servant in Hampton Road, and from whom she told him he stopped the first-named prisoner and asked him who he was and what he was doing, and he replied that he was travelling for the American Portrait Company, and the other two came up and said they were doing the same thing. He asked them to show him some proof, and one of them handed him a card, which bore the following: "The American Portrait Company, Home Office, 63, Turner Street, London, E. Presented by —." They refused to give him any further information, and he took them to the station. He had made enquiries at 63, Turner Street, which was a private house, and was told that they paid the woman there 3s. a week to take in letters, and had a little room where they occupied for about an hour in reading letters. He had been able to finish his enquiries, and he asked for a remand. Prisoners were remanded for a week, and bail in £10 was granted.

**ALLEGED Stealing.**—At North London Police Court, on Saturday, Henry Cox and Frederick Rainbow, residing in the same house, Turner Square, Hoxton, were charged with being concerned in stealing and receiving four cameras, three dark slides, and a quantity of wooden and brass camera fittings belonging to Messrs. Houghton, Limited, photographic appliance manufacturers, Tudor Road, Hackney. Mr. Herbert Holmes, manager at the works, said Rainbow had been employed by him for the past four years. In consequence of certain information received, he, on Friday, with Detective Saunders, of the J Division, to the Islington Camera Market, where there is a miscellaneous sale every Friday. On the stall he saw a reversing-box, a dark slide, turn-table, and a quantity of other photographic appliances and fittings which he (witness) identified as having been stolen from Messrs. Houghton's store-room. The detective questioned Cox, and he said he bought things in Petticoat Lane from a dealer. But Cox was taken into custody and his house searched, when there was found a camera slide, a camera-holder, and a quantity of brass fittings. And the rooms of Rainbow, Detective Cruickshanks discovered four cameras, two slides, and a quantity of brass and wooden camera fittings, also claimed as Houghtons' property. After this Rainbow was given into custody. Cox declared that Rainbow made him present of the things, and had no payment for them; and he said he did not know by whom Rainbow was employed. The police asked for a remand so as to make further inquiries, and this was granted.

**THE West London Photographic Society**, owing to its large increase of membership, has found it necessary to return to its quarters at the Broadway Lecture Hall, Hammersmith, W., which has been extensively redecorated for its use. The Hon. Sec., Mr. G. F. Perrins, has resigned, owing to pressure of business, and Mr. Jordan R. Lynch, junior, of 160, Holland Park-avenue, V, has been elected Hon. Sec.

**THE Awakening of China.**—A guide to photography in the Chinese language is to be published by the Presbyterian Mission Press, Tientsin, North China. The native author is Mr. Y. T. Woo, who, of Western inclinations to the extent of offering European advertisements space in his work.

## News and Notes.

**R.P.S. LECTURES at the New Gallery.**—The following are the forthcoming lectures at the Royal Photographic Society's Exhibition:—October 20: "A Winter Holiday in Greece," by Albert Cheese. October 22: "Some Churches of Central France" (Details of the Architectural Features taken with the telephoto lens, by Ernest Marriage, F.R.P.S. October 25: "English and Continental Scenes in Colour" will be shown by the triple projection lantern, by Sir W. de W. Abney, K.C.B., D.C.L., F.R.S. The concluding lecture on October 27, the closing night of the exhibition, will be on "Winchester Cathedral," by S. G. Kimber.

**"PHOTO-CHEMISES."**—The "Daily Mail," to which we look for early information of great events, notifies its readers of a new departure in lingerie for which, it appears, photographers are responsible. The innovation is an article of infant attire, called a "photo-chemise." Made of the finest possible lawn, with hand-worked embroideries and lace insertions, it is the design of the head woman of a well-known firm of lingerie purveyors. From time to time she was asked by fond mothers whose babies were about to be photographed for some light little garment that could be worn by small boys and girls whose chubby limbs it were a pity to hide beneath the conventional frock, socks, and shoes. The chemise she invented has a low-cut neck and is sleeveless. Straps of ribbon support it across the shoulders, so arranged that they slip off over the fat little arms. One guinea is the price of a tiny chemise as fine as a cobweb and as soft as thistledown.

**The Linked Ring at Home.**—On Tuesday evening the Linked Ring were at home to their friends at 5A, Pall Mall East. The programme of the evening was, as usual, informal in its statement of the enjoyments provided by the Linked Ring for its guests. It announced—

At Intervals in the Talk, the following Gentlemen .  
will Amuse and otherwise Interest the Audience .  
with Singing: with Piano Playing: by Comic . . .  
and Tragic Reciting: and by other Performings .

the gentlemen being Mr. Arthur Helmore, Mr. Reginald Groome, Mr. Victor Marmont, Mr. Cavendish Morton, Mr. George Parlbly, and Mr. Walter Churcher—the last on the list, with the evergreen "Commercial Value of Art," and the first, Mr. Helmore, with the most delightful imitations of popular actors as they might be in other walks of life; Miss Terry, as an A.B.C. waitress; Mr. Lewis Waller, as a footman; and Sir Charles Wyndham, as a waiter. A large company, which included many well known people in the photographic world, spent the most enjoyable of evenings, and at its close Mr. Craigie, the ever suave secretary of the Salon, was accorded the heartiest expression of thanks by those who once again had enjoyed the welcome hospitality of the Linked Ring.

**Bioscope Serials: A New Departure.**—The Charles Urban Trading Company, of 48, Rupert Street, London, have inaugurated a new departure in the Bioscope profession—the serial publication of "Films." This week are published the first two numbers of "Bonnie Scotland," a pictorial representation of all that is lovely and wild and weird in that land of historic associations. This series will form, when complete, the most comprehensive animated representation of Scotland and its beauties ever published.

**Bristol Photographic Club's Exhibition.**—This exhibition remained open for seven days, and was a notable success, both from the pictorial and the public point of view. The attendance rose steadily day by day until it reached over 1,000 on the closing day. During the exhibition three lectures were delivered, and these proved a most attractive feature. On the Tuesday, Mr. Melton Fisher, the well-known artist, gave a lecture on "Photography in Relation to Painting," a report of which we hope to publish later on. On Thursday Mr. S. G. Kimber, of the Southampton Camera Club, gave a lecture on "Winchester Cathedral." The splendid lantern slides with which this was illustrated, were clothed with life and romance by the interesting (often humorous) discourse which accompanied them. Owing to the large number of people unable to get into the lecture room, Mr. Kimber kindly ran through his slides a

second time. On Friday Mr. Ernest R. Cook, D.Sc., of Bristol, gave an address on "How Photography Aids Science," profusely illustrated by lantern slides. Several lantern shows were given each day, the slides being selected from those sent in for competition, and others lent by "The Amateur Photographer," "Photography," and Messrs. Sanger Shepherd and Co. (in natural colours).

**MATTOS, LTD.,** has been formed to take over the manufacture of Mattos papers, etc. Mr. P. Leuthardt-Thornton becomes managing director, under whose control the company will introduce new lines, such as Mattos sensitised wood, linen, silk, and satin. All materials will be offered from quarter-plate size upwards, so that the amateur will be able to use also the other textures, besides papers, at a reasonable price.

## Correspondence.

*\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*\* \* We do not undertake responsibility for the opinions expressed by our correspondents.*

### LEAKY STUDIOS.

To the Editors.

Gentlemen,—I have so often had good advice and information from the B.J. that it is both a pleasure and a duty to give it in return, when I can. There are frequent queries anent leaky studios, and the subject is up again on page 803 of the last number of the JOURNAL.

For years my greenhouse was a source of annoyance from persistent leaking—the old story of putty cracking. A couple of years ago I saw an advertisement of "Carson's Plastine," which was recommended for greenhouse glazing, and, knowing the high character of the firm, determined to try it.

It has been a complete success, and, in spite of heat and drought followed by heavy rain, I have had no trouble. "Plastine," I would add, is a substitute for putty, and is used in the same way. I hope that this information may be of assistance.—Believe me, yours faithfully,

J. E. GUBBINS,

Westward Ho! R.S.O., North Devon.

Lieut.-Colonel.

### THE STABILITY OF PYRO AND SODA DEVELOPING SOLUTIONS.

To the Editors.

Gentlemen,—In view of the present discussion as to the use of sulphite as a preserver and stain-preventive, a brief history of the chemistry of the question may not be amiss. The action of sulphites in this direction has always been more or less "wropt in mystery" since they were first proposed by Berkeley. The conventional view was that the sulphite, in presence of organic reducer, is preferentially oxidised to sulphate by the air, the reducer thus being severely let alone both before and during development. But the following will show that the action is by no means so simple.

Bigelow, in 1898, found that the aerial oxidation of sulphite was greatly retarded by the addition of certain organic substances, as mannite. These were termed "negative catalysts," and their action was confirmed, and the number extended by S. W. Young in 1902. In 1903 Titoff showed that the addition of minute—in some cases extraordinarily minute—quantities of certain metallic salts greatly accelerated the oxidation, whilst the negative catalysis found by Titoff was due to the inhibition of this positive catalysis, those organic substances in question combining with, or altering, the metallic salts. The most active of these were the salts of copper and iron. Further, in 1903-4, a lengthy investigation by Lumière and Seyewetz showed, as was to be expected, that in presence of developing agents (amidol, etc.) the oxidation of sulphite is greatly delayed. Evidently the two substances together exert a mutually preservative action. In 1903-4 the writer, with Mr. C. E. K. Mees ("Zeit. Wiss. Phot.," 1904, II, 5-11), made an investigation of the chemical changes involved, especially in regard to the hydro-

quinone developer. Andresen had previously stated that hydroquinone *plus* sulphite reduced more silver bromide than hydroquinone alone, and apparently considered that a quinone sulphonic acid was formed. We found that the quinone formed by oxidising hydroquinone with silver bromide was reduced to hydroquinone, by either neutral sulphite or alkali separately, or by a mixture of both. With alkali alone the reduction was not complete, there being a separate oxidation by air leading to tarry products. In this case, the alkali is oxidised by the quinone to a peroxide.

hydrogen peroxide being found, whilst with sulphite, hydroquinone and dithionous acid are obtained.

The dithionous acid is then probably further oxidised to sulphate. It will be seen that from this it follows that the preservative action of sulphite is due to its reconvertng, at its own expense, the oxidation product of the reducer. This action has been shown to follow in other cases (Chem. Soc. Journ., 1906, August). We thus have a complete cycle of changes involved, of considerable interest chemically, and somewhat important to photographers. The main practical conclusions so far appear to be (1) that neutral sulphite and pyro (or other reducer) is the most stable mixture; (2) that the sulphite should be adjusted proportionately to the amount of reducing agent; (3) Impure sulphite, etc., is strictly to be avoided, owing to the possibility of metallic impurities.

It may be remarked, that whilst acids tend to preserve organic reducers, yet an acid sulphite is by no means the best preservative, since the strength of the sulphite is continually decreasing. Further, from the writer's experiments, sodium sulphate, *pure*, is a quite neutral substance in development, sulphite, a slight restrainer, when the quantity is very great.

On the whole, I think these facts tend to support the procedure you propose rather than that of Mr. Bennett; personally, my own experience has always been in favour of mixing the pyro with pure neutralised sulphite.—I am, yours, etc.,

Marburg a/L., Germany.

#### PHOTOGRAPHIC RESEARCH.

To the Editors.

Gentlemen,—Mr. C. Welborne Piper's quotation from the second condition under which the P.C.U.K. is prepared to make grants of money in aid of photographic research, is quite correct, as far as it goes. I should be glad, however, if you would allow me to give the paragraph in its entirety:—

(2) A grant must not be expended on the purchase of permanent apparatus, *except by special permission of the Research Grants Sub-Committee.* (The italics are mine.)

The reason for this reservation should be obvious. There is nothing, as far as I am aware, to prevent an applicant asking for this "special permission," and, as the object is to promote research, not to put obstacles in its way, he may rely upon his request receiving every consideration.—Yours truly,

F. A. BRIDGE,

Hon. Gen. Sec. and Treas., P.C.U.K.

East Lodge, Dalston Lane, London, N.E., Oct. 15, 1906.

[Mr. Piper, in his letter, did not pose as a prospective applicant.—Eds., B.J.B.]

#### LANTERN SLIDES OF ENGLISH CATHEDRALS.

To the Editors.

Gentlemen,—The Rev. S. E. Teignmouth Shore, M.A., Magdalen College, Oxford, who is in charge of the Dacca Hostel in connection with the Oxford Mission to Calcutta, will be returning to India early in November, and is anxious to take back with him some lantern slides of London and Oxford, and English Cathedrals.

Will you kindly allow me, through the medium of your journal, to ask if any of your readers, especially members of the P.P.A., have any spare lantern slides of these places.

If they will kindly send them to me, carriage forward, before October 31, I shall be extremely grateful.—Your faithfully,

ALFRED ELLIS.

Ellis and Walery, 51, Baker Street, London, W.

## Answers to Correspondents.

**\*\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.**

**\*\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**

**\*\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.**

**\*\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, &c. Two unmounted copies of each photograph must be sent with the original.**

#### PHOTOGRAPHS REGISTERED:—

R. G. D. Hood, 41, Wallace Street, Grangemouth. *Photograph of the Opening of the New Docks at Grangemouth.*

J. Bellman, 13, Victoria Road, Whitehaven. *Photograph of the New Carnegie Free Public Library, Whitehaven.*

**STUDIO SIGNS.**—Would you kindly tell me in the Query Column where I can obtain those little cardboard notices bearing such words as "To the Studio," "Dressing Room"?—MANAGER.

From any of the large dealers such as Marion and Co., F. Lowfield, etc., or from shopfitters such as Potter, Aldersgate street, London, E.C.

**GLOSSY BROMIDE.**—Will you kindly let me know how to treat glossy bromide paper to prevent surface markings. We have just started to deal with glossy bromide for postcards in fairly large quantities, and we find it very tiresome having to treat the cards individually to remove the markings. Is it possible to prevent same by special treatment, or the addition of something to the developer? I should be much obliged if you can help us in this matter.—A. F.

Try the addition of a little alcohol (spirits of wine from a grocer who sells Gileby's spirits), or use the "Nobra" developer specially issued for glossy paper by the Kodak Company.

**DEPTH OF FIELD.**—Will you kindly inform me of any tables in which I can find, or how to calculate, the practical depth of focus of a Voigtlander "Heliar" lens of 6½-in. equivalent focal length (full aperture 4.5)?—Toxo.

See the article by Mr. Welborne Piper in our issue of December 22, 1905, in which you will find the formulae. Mr. Piper's "First Book of the Lens" will also give you much information.

**M.Q. DEVELOPER.**—Would you kindly give me receipt for metallic hydroquinone developer for plates and paper which can be used repeatedly?—T. BRISTOL.

No developer can be worked *ad infinitum*, but you will find the following a very satisfactory formula:—

#### No. 1.

Metal	40 grs.	5 gms.
Hydroquinone	50 grs.	6 gms.
Sulphite of soda	120 grs.	14 gms.
Bromide of potassium	15 grs.	2 gms.
Water (boiled or distilled)	20 ozs.	1,000 c.c.s.

#### No. 2.

Caustic potash	180 grs.	21 gms.
Water (boiled or distilled)	20 ozs.	1,000 c.c.s.

For use, take equal parts of No. 1 and No. 2.

**TONING P.O.P.**—In winter, to save washing, I omit the alum bath before toning P.O.P. I wash, tone, fix and wash for two hours, then give alum bath for ten minutes, then wash an hour. Considering its chemical action, would such treatment be better or worse for the prints than the alum bath before toning?—S.

So long as the prints are well washed between treatments

with alum and hypo, there is nothing to choose between the two so far as permanency is concerned.

**INQUISITIVE READER.**—1. The Westminster Co.'s arc lamps are used. 2. Any ordinary curtains are used. 3. Not so suitable as the enclosed arcs.

**LENS QUERY.**—I should feel greatly obliged if you could reply to the following:—Having purchased a Ross 5 by 4 S.A. doublet, should esteem it a favour if you could inform me what it is most suitable for—architecture, portraiture, or copying; also under what conditions it will take a larger plate than the lens is marked.—**LIFELONG READER.**

The lens is now an antiquated one. It was introduced something like forty years ago for general work, except portraiture, and has long since been superseded by other forms of lenses, and has little or no commercial value at the present time. It will cover the size marked upon it, and we don't expect it will do more than that. Why not try it, using a small stop, and see for yourself. "S.A.," we may tell you, means small angle. Three lenses of this kind used to be made, and were designated—small angle, ordinary angle, and large angle.

**POSTCARD.**—The marks on your cards are certainly not due to any impurity or addition to the water, nor are they caused by the prints not being moved during fixation. They are abrasion marks caused by the rubbing of one postcard over the other. As you have met with them on two brands of paper it is obvious that it is faulty manipulation on your part. You give no data as to developer employed nor time of washing, but it is obvious that in some way you have so softened the gelatine that it will not stand much. We should advise you to use the chrome alum fixing bath given on p. 727 of our issue of September 14.

**A. G. B.**—We do not know the article on the British market. Messrs. Maron are the most likely people to tell you of it.

**CARBON TRANSPARENCIES.**—You kindly gave me instructions for the obtaining of stainless images with a process formula for metolquinol which I found quite efficacious, and desire now to thank you. Ever since I took up making enlarged negatives by means of carbon transparencies I have had trouble with the substratum. The lecturer from whom I obtained my instructions stated that he used collodion for that purpose, and mentioned nothing about any preliminary preparation of the glass. My experience was when I used the collodion coated on plain glass, that the collodion washed up in developing in the hot water. I am now using a wash of insoluble gelatine on the glass, after which I coat with the collodion; but this takes so much time to prepare the glasses that I am asking you to say whether I can ensure the collodion adhering in the hot water without such previous preparation, as apparently my informant did. Shall be much obliged for any information.—**J. H. WINGRAVE.**

The usual method of making carbon transparencies for enlarged negatives is to first coat the glass with the following substratum: Nelson's No. 1 gelatine, 1 ounce; water,  $\frac{1}{4}$  pint. When dissolved, sufficient solution of bichromate of potash is added to give the solution a golden tint. The plates are then dried in the light to render the gelatine insoluble. The exposed tissue is also coated with collodion and allowed to dry before squeegeeing it on to the substratum. With this method of procedure the best results are obtained, and there is no fear of the film washing up with the development. There is really very little trouble in coating the glass with the substratum. The only way to prevent the collodion from washing up, when the substratum is not used, is to roughen the edge of the plate all round, about the eighth of an inch, with a piece of ragstone, and use care that the collodion film does not get injured. The roughening of the glass is really more trouble than coating it with the substratum.

**PHOTOGRAPHS ON CANVAS.**—I am contemplating running a line of oil paintings on photographic basis. I am aware that it is quite possible to make this basis on artist's canvas, on stretcher, but I am in ignorance of method of working same, and also of the formulæ. Would you be so good as to supply me with the necessary particulars?—**NOSMADA.**

We believe the canvas is sized twice and coated with ordinary

paper emulsion. We should also think that a celluloid varnish sprayed over the last coat of size would be an advantage.

**PHOSPHORESCENT MATERIALS.**—May I respectfully ask if you can favour me with information regarding any phosphorescent substance which will retain its luminosity for a fairly lengthy period?—**PHOSPHOR.**

Balmain's luminous paint, from any large chemist.

**BROMIDE.**—1. Your experience is unusual. You might try changing the brand of paper. A very soft water supply will cause blisters. Some Epsom salt (say, 20 grains per gallon) would help matters if this is the cause. 2. There is none. Hand washing is the best course. 3. We cannot understand your query. Water alone will not fix.

**SAFE LIGHT.**—In your issue of July 27 you gave particulars of a safe light for colour sensitive plates. Will you advise me in your next issue: 1. Where can I get a Stenger's lamp, and cost of same? 2. Where can the chemicals for making the solution be obtained?—**R. E. WESTON.**

1. The maker of this lamp is Adolf Schuch, Electro Technische Fabrik, Worms am Rhein. The price is 10s. Lamps of similar construction can be obtained from Watson and Sons, High Holborn, W.C. 2. The dyes recommended by Dr. Stenger are those of the Hoechst Works, and the English agents are Fuerst Bros., 17, Philpot Lane, E.C.

**LEAD TONING.**—Kindly let me have formula for a lead toning bath without gold.—**HENRY LONG.**

The usual formula is

Lead acetate or nitrate .....	$\frac{1}{2}$ oz.
Hypo .....	4 ozs.
Water .....	20 ozs.

Dissolve the hypo and add the lead salt previously dissolved in water. The prints may or may not be washed before toning. It is, of course, extremely doubtful whether prints toned by this method are permanent.

**SILVER STAINS.**—Would you be so kind as to let us know the formula for removing silver stains from negatives? We have tried the iodine (cyanide) solutions, and find this reduces the negative without removing the stains.—**F. W. and S. LONGMAN.**

A great deal depends upon the age of the stains. Recent ones will frequently yield to rubbing with pumice powder and subsequent fixation in a strong acid hypo bath. Another method is to rub them with a tuft of cotton wool soaked in a solution of ammonium persulphate, rendered alkaline with ammonia, or it may be rubbed over with a solution of

Potassium bichromate .....	2 grs.
Common salt .....	20 grs.
Water .....	1 oz.

Then wash and fix in a 1:4 ammonium sulphocyanide solution. Possibly also a solution of

Potassium cyanide .....	10 grs.
Sodium sulphite .....	50 grs.
Water .....	1 oz.

will remove the stains without reducing the negative.

**S. and Co.**—We fear it is little use our advising you. We can only tell you that 15s. for each negative and one print plus out of pocket expenses would be charged by many photographers with, say, 2s. 6d. for every subsequent print. We suggest that as a member of the Professional Photographers' Association you might obtain the confidential advice of some of its members.

**SHOP WINDOW.**—Will you kindly give me address of the (clock-work) mechanical arrangement for dropping picture postcards for shop window purposes. Shall look in "Answers to Correspondents" column for reply. In anticipation, thanking you.—**W. E. B.**

Potter and Co., shopfitters, Aldersgate Street, London, E.C. **MIDGET REPEATER.**—We are not familiar with the working of the apparatus. Why not write to the maker of it for the information you desire?

**ENAMELLING PRINTS.**—Could you kindly oblige me by publishing the proper way to do gelatine enamelling, and the solution to use; and also the way to raise the enamel prints when mounting?—**B. R.**

The method has been published over and over again in the JOURNAL and in the ALMANAC, and we cannot afford much space

to again describe it. In brief, it is: Thoroughly clean glass plates and rub them over with French chalk. Coat them with enamel collodion, and when it has well set put them in cold water until all greasiness disappears. Have ready a dish of warm gelatine solution—say, one ounce of Nelson's photographic gelatine to a pint of water. Immerse the plate and print in that, bring into contact, remove, and squeegee in contact, and allow to dry. The prints are pressed up in an embossing press, which may be had of any of the dealers.

**ARTIST.**—We can only say that the prospects in Canada are extremely good. Probably touring photographers would find a lot of business in the North-West, but they would have to rough it.

**COPYRIGHT.**—I have had a 1-1 transparency brought to me, from which I have been asked to make enlarged negative for printing copies for sale. The subject is "Via Dolorosa," and is stated to have been taken from a picture by Raphael in the National Gallery about twenty years ago. Shall I be running any risks whatever in making a negative and printing from same copies for sale?—J. H.

It is impossible for us to say without knowing the precise history of the transparency. All we can tell you is that though there may be no copyright in the painting, there probably is a registered copyright in every photographic copy of it. If you have the original negative made of the painting you will be quite safe, although if it has been transferred to you without assignment of the copyright, the latter is now destroyed.

**COPYRIGHT.**—I have taken two photographs, and I wish to make them copyright; will you kindly let me know how to go about it, and what it will cost?—BROWN.

If you send 1s. 7d. to our publishers, with two copies of the photographs, they will register the copyright for you. You will find other details of copyright in the article on the subject in the current ALMANAC.

**HALF-TONE NEGATIVES.**—Will you kindly let me know, through your next week's issue, which you consider the most satisfactory way to make three-colour half-tone negatives? Is making the negatives with dry plates and then making transparencies from these, or paper prints and copying from them with an arc lamp, or by making the negatives by the direct collodion emulsion the most successful way?—AN INTERESTED ONE.

The simplest and most satisfactory way now is to make screen negatives direct on dry plates. The plate for the blue filter, yellow printer, can be an Ilford "Half-tone" plate, the plate for the green filter, red printer, and red filter, blue printer, can be Wratten's panchromatic plate. Collodion emulsion is far too much trouble in this work, if not done on a large scale, to get regularly. Some things, of course, must be made indirectly, because the contrast will be too great to allow of a cross-line screen to be used at the same time as making the negative; but paper prints should not be made afterwards, but positives on glass, as paper prints are liable to stretch or shrink, and will give bad register.

**BUSINESS QUERY.**—At times there are customers who purposely have sittings, and give an order, or obtain proofs (by some means) that they never intend to pay for. How should such be treated when they are not worth to take to court for debt? I notice one ticketed the photograph in his case with a label on it. Is it judicious to do that with any words at it, or is it *infra dig.* in all circumstances?—S.

If your customers serve you in that way your only remedy is in the county court; there you will recover the money. Although the portraits may not be paid for, the copyright in them belongs to the sitters, therefore you have no right to exhibit them or use them for any purpose of your own. Why not obtain payment at the time of the sitting? You would then be on the safe side.

**PORTRAITURE.**—I should be very much obliged if you could inform me why it is that I cannot get the faces of persons out light. I have tried different exposures, thinking that is the reason, but it makes no difference. I have got a London stereoscopic lens, and I use shop-bought developers ready mixed, 1 and 2. I should be very much obliged if you could give me a good recipe for a developer for studio work.—J. D.

You had better use a developer the formula for which is given by the makers of the plates you use. We cannot, in this column, give elementary instruction in photography. You should get a beginner's work, such as "Elementary Photography," by Hodgkinson. Your dealer will supply it.

**BOOKS WANTED.**—Would you kindly inform me of all the best books suitable for an operator, such as "Art as Applied to Photography," "Light and Shade," "Posing," etc., and from which they could be obtained. Thanking you in anticipation.—H. C. CLARKSON.

"Practical Essays on Art," by John Burnet, three parts, 2s. 6d.; "Artistic Lighting," by James English, 2s. 6d.; "Lighting in Photographic Studios," by P. C. Duchochois, are all good works. You will find a list of other books on page 1064-7 of the ALMANAC for the current year.

**TRADE DISPUTE.**—About three months ago I sent two half-plate negatives to Mr. —. He was to make me two dozen 12 x 10 from same at 1s. each. I received later a letter stating he would advise me to have the extra special quality, and I could depend on getting very best work, and the price would be 1s. 3d. each. I unmounted. This I agreed to, and said I would send on balance in due course. I received the enlargements, but some of them were so dreadfully black my customers would not accept them at any price. So I returned a matter of five or six and explained matters to him, and he said he would do me some to replace them if I would send on balance of account. I do not feel inclined to send money on until I see what those will be like to replace. I have written many times for negatives, as I cannot wait for enlargements. I have also written to the inspector of police, and they say they can do nothing for me.—H. J. M.

We should think the best plan would be to pay the money you owe and then demand the prints agreed to be done, and also the negatives. If they are not then forthcoming sue in the County Court for the value. Yours is a case that the Professional Photographers' Association would quickly settle for you if you were a member.

**J. T.**—You should not take less than 10s. 6d. each.

**RETOUCHING BROMIDES.**—Could you inform me of any good book published on the subject of "B. and W. Finishing of Bromides"? I have tried for some time past to meet with a book treating fully with such a subject, but without success. If you can recommend any work of the kind you would greatly oblige. E. N. C.

The best book on the subject is Johnson's "Retouching Negatives and Photographs," published by Marion and Co.

**THE Invertol Gas Light.**—In reference to our note of last week, the Invertol Company write: "We are greatly obliged by your mentioning our new inverted incandescent light for country districts in your issue of the 12th inst. Your journal has evidently a very wide circulation, for we have received inquiries about this light from all parts of the country, but we have to point out, in reply to the inquiries, that our inverted incandescent light is obtained by vaporising petrol, not paraffin."

[We regret having misrepresented the company's speciality.]

**NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## The British Journal of Photography

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

### TERMS OF SUBSCRIPTION, Post Free

(UNITED KINGDOM AND THE CHANNEL ISLES).

One Year ... 10s. 10d. Half Year ... 5s. 5d.

Quarter Year ... 2s. 9d.

## SUMMARY

Ten days must elapse before the closing of the exhibition of portraiture by Mr. Fredk. Hollyer at Kensington. A review of the exhibition by Mr. F. C. Tilney appears on page 844.

The Society of Colour Photographers. The rules drawn up by the committee to be submitted to a meeting on November 14 are given on page 849.

The total now subscribed to the Sandell fund is only a few shillings short of £100. (Page 849.)

In reviewing the newly-issued "Photographs of the Year," we call attention to the imaginative writings of Mr. A. C. R. Carter. (Page 850.)

Professor Max Wolf, of Heidelberg, has published the first of a series of stereoscopic photographs of the heavens, showing in wonderful relief the detail of the stars. (Page 854.)

On Tuesday evening last the ninth Traill-Taylor memorial lecture was delivered by E. Walter Maunder on "Photography in the work of the Greenwich Observatory." A report appears on page 850.

How a photographer secured good local advertisement on installing the arc light into his studio is told on page 843.

The considerations which should guide the photographer in using his own or a fancy signature in his business are given on page 845.

Means of introducing red rays into the light of the mercury-vapour lamp or of supplementing its redless light are mentioned on page 849.

Developers for P.O.P., two-colour photography, and a new type of all-size focussing finder are among the patents of the week. (Page 851.)

A pinatype method of making reversed negatives is advocated by an Austrian writer. (Page 845.)

Formulae for a silver phosphate emulsion have been published by Herr Valenta. (Page 846.)

Dr. Lüppo-Cramer announces a sulphocyanide reducer giving the effect of persulphate. (Page 846.)

## EX CATHEDRA

### The Salon at the Royal.

In the newly-issued "Photograms of the Year," reviewed on another page, there is a notorious perversion of fact on the part of Mr. A. C. R. Carter, the author of the "chief critique." Mr. Carter states:—"The Royal is no longer a weak Salon, no longer a warehouse for the despised and rejected of that institution, but an annexe, a complement to hold many examples acceptable by, but crowded out of, the Salon. . . . With a strong leaven of Salon exhibitors . . . the show is enriched, etc." All this implies a state of things that is positively the reverse of fact. It is ill-judged special pleading. Such a back-stairs championing of a society artistically down on its luck is not likely to do it so much good as it will do good to its adversary. Mr. Carter gives a dozen names as those of exhibitors who have been seen at the Salon, and who are here (at the Royal) in welcome force. But most of these have been constant exhibitors at the Royal for years, and six of them are actually members of that society. It is difficult to understand how such a distortion of the facts should have escaped the scrutiny of the editor of "Photograms."

\* \* \*

### Ancient Photographic Lenses.

We suppose there must be hundreds of photographic lenses in existence which were made in the earlier days of photography, for we are constantly being consulted as to their properties by those who have perchance become possessed of them. Many of the instruments have long since become obsolete, yet many are still very useful for some purposes. Last week we replied to a correspondent, who said he had bought a lens on which was engraved, "Ross SA Doublet," a form of lens introduced by the late Mr. Thomas Ross very many years ago under the name "Actinic Doublet." Three series of it were made: "SA," small angle; "OA," ordinary angle; and "WA," wide angle. Its field was somewhat round, and there was a falling off of light at the margins of the plate. The modern "RR" has now taken its place. The old orthographic, many of which are still in existence, was an invention of Petzval. It consists of a large front lens similar to the front combination of the portrait lens, with a small back one, which is a dispersing lens. This lens gives marginal distortion of the pin-cushion form; otherwise it is a serviceable lens, and has an aperture of about f/10. There is also the "Triplet," which is an excellent lens, and is still listed by one of the leading opticians, and one that we are sometimes asked about. It consists of three combinations, the centre one being much smaller than the others, and the back larger than the front. It was introduced some forty or more years ago. In the early

days a French house put upon the market a portrait lens of the Petzval type, in regard to which our advice is occasionally asked. This lens was supplied with two additional lenses which could be screwed in the centre of the mount. The one lengthened the focus of the combination, so that larger pictures could be taken with it; the other shortened the focus. So that, with it, three different foci could be obtained with the same instrument. This lens, we believe, is no longer made.

#### **The Diaphragm as Datum Mark.**

There are thousands of portrait lenses of the Petzval form that were made in the very early days of the art still in existence and use, and many of them are excellent instruments, particularly those bearing well-known makers' names. Those made in the pre-carte and -cabinet days had a much rounder field than those of more modern construction. They were not fitted with Waterhouse diaphragms, as these stops were not introduced till about 1860, and then an additional charge was made for them beyond the price of the lens. But in the sixties fitting of all portrait lenses with these stops became universal. Hence it may be taken for granted that any portrait lens that is not fitted with these stops is at least not less than forty years old, and may be much older. It does not follow, however, that because a lens is fitted with Waterhouse diaphragm that it was made within the last forty years, because many of them have been fitted with these stops since that time. As we have just said, many of these old portrait lenses are excellent instruments, but we would counsel all purchasers of them not to do so without first trying them, particularly if they bear no maker's name. We have more queries with reference to old portrait lenses than any other as to what they should cover, etc. But that can only be ascertained by a trial. There are other kinds of early lenses, but those above referred to are the principal ones that are likely to be met with at the present time.

#### **Sulphite of Soda and Development.**

The interesting letter by Mr. S. E. Shepherd in our last issue confirms what we said in a previous note—viz., that there is a great deal of mystery surrounding the behaviour of the various ingredients of the developer. In the developer it is clear that sulphite does not act in the way it is popularly supposed to do, and, for our own part, we are fairly well convinced that sulphite in solution is subjected to changes of somewhat a different, or, at any rate, a more complex, nature than those commonly assumed. In these circumstances we are not disposed to speculate as to the probable

condition of affairs in the developer solutions we have commended until some direct confirmatory evidence is available. It is interesting to note that others have had the same experiences as ourselves, and Mr. S. A. Herbert's letter of October 12 shows that the keeping qualities of developer are greater than we have ventured to ascribe. Fifteen months is about as long as anyone is likely to wish to keep a pyro soda developer, and very much longer than one can usually be trusted for. We are glad that our notes have aroused so much interest, and shall welcome any further evidence or experiences that may be forthcoming.

#### **Metric Measures.**

All advocates of reform in weights and measures will watch with interest the adoption of the metric system by Messrs. Kynoch, Birmingham, who are to employ it in all departments of their firearms factory, not excepting the counting house and pay-office. Mr. Arthur Chamberlain, the chairman of the company, is convinced of the advantage of the system to the business, and one cannot suppose a commercial undertaking such as Kynoch's making the move except on strict economic grounds. In their opinion metric measures are more effective and less expensive or tedious than the old ones, and we hope they will be adopted. We shall be anxious to see the influence of their departure in other industrial firms, and we hope the step will be one towards the extrication of the tangle of British weights and measures. We are pledged to decimalism as the perfect system for every industry, but we are in hopes of some day witnessing supersession of the many ambiguities which attach to our measures at present in use.

#### **A Matter of Weights and Measures.**

It does not surprise us to see one of our correspondents on the subject of the pyro soda developer becoming somewhat confused with regard to the division of the ounce. He suggests that if our formula showed 120 grs. instead of 160 it would have been more convenient, as four weighings would have emptied the bottle. Unfortunately this is not the case, for 120 grains is more than a quarter of an ounce avoirdupois, which is the ounce by which pyro is sold. An avoirdupois ounce does not cut up conveniently into a number of equal parts, and if it did we should hardly be disposed to advise it being weighed out in such parts, the errors of weighing would invariably leave either too much or too little in the bottle for the last part, and the advantage assumed by our correspondent would hardly be felt in practice. A quarter of an ounce is nearer 110 grains than 120, and if this quantity is taken the solution can be made up to an even convenient number of ounces.

### **THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1907.**

Edited by GEORGE E. BROWN, F.I.C.

THE forty-sixth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,616 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1907 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### **THREE-COLOUR PHOTOGRAPHIC PRINTING PROCESSES,**

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1907 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1907 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, and, wherever practicable, features of an informative nature will be added.

**\* \* IMPORTANT NOTICE.**—Our publishers ask us to inform Agents that it will be as well to place their orders for copies immediately, as the issue is always booked before publication, and a second edition will not be printed.

always best from the economical point of view to so just your solutions that they may fill the bottles available, and when English measures are used all solutions would contain some definite number of grains per ounce. The strength of the pyro solution we have recommended is 8 grains per ounce. This makes 160 grains to a 20 ounce bottle. 110 grains would only make  $13\frac{1}{2}$  ounces of solution, and that is  $2\frac{1}{2}$  ounces less than the capacity of a 20 ounce bottle, which is the nearest size. It is better economy to fill that 16 ounce bottle and weigh out 128 grains of pyro while you are about it, and it is even better economy to use a bigger bottle and prepare a larger stock. In practice we have found 10, 20, and 40oz. bottles to be the most convenient sizes for photographic purposes, and we must all formulæ to fill such sizes. With modern crystalline pyro there is no difficulty in weighing small portions, but if the old variety is used, and the whole ounce dissolved at once, 55 ounces of stock solution results, and a 60oz. bottle is necessary.

#### The Word

The letters from Dr. Murray of Oxford "Photography," some time ago on the origin of the word "photography" are probably within the remembrance of our readers, who will recollect that the earliest discovered use of the word is by Sir John Herschel in March, 1839. There is no evidence of the employment of the word earlier than this, although some writers have assigned the credit of originating the term to Nicephore Niepce. At the time pointed out wherein the error of this assumption lay, and no further research is needed to prove the fact that Niepce did not, in the passage which was cited, employ the word "photography." Yet it may be well to quote a comment in the writings of Robert Hunt, the first historian of photography, which negatives the view that it was Niepce who christened the art of the camera by its present name. It occurs in Hunt's "Poetry of Science," published in 1848, and runs as follows:—"Photography is the name which the art of sun-painting will be for ever known. I regard this as unfortunate, conveying as it does a false idea, the pictures not being light-drawn. Could we adopt the name given by Niepce to the process, the difficulty would be avoided, since heliography involves the hypothesis, and strictly tells the undeniable fact that the pictures are sun-drawn." As Hunt was the writer of the time most intimately acquainted with the writings of the contemporaries, it is clear that the term photography was understood at that time to have come from some other source than Niepce.

#### Opportunity for Advertisement.

We read in a Northern paper how a photographer availed himself of a chance to bring his business to the attention of the public which many would have passed over. Having installed the electric arc in his studio for portraiture, he invited the municipal lighting committee to witness a demonstration of its capabilities. These gentlemen and their friends attended and expressed themselves pleased with what was shown them in the way of an actual demonstration of the powers of the light. According to the local paper, "The experiments proved that the highest class of photography can be achieved at any hour of the day by means of electric light." We do not know what better references to himself a photographer can want than this, and his alertness in taking use of the occasion is worthy of the methods which the professionals such as Mr. J. S. Strauss, of St. Louis, have employed over and over again. We imagine that the expense of entertaining the visitors would be refunded to him in the orders received from those who accepted of it. His example may well be followed by others installing electric light in their establishments.

#### Improvers in Photography.

Last week we had something to say about the exceedingly small salaries at which some photographers expected to obtain experienced assistants—that is, judging from those occasionally offered in advertisements. Apprentices are at times taken for a term of years with premiums or for quite a nominal wage, more with the idea of getting the labour for next to nothing than teaching the trade. When out of the time the apprentice often finds that he or she really knows but very little of the business. Hence we see advertisements for "improvers." Now, improvers are expected to take situations at a very small salary, although at the same time they are expected to be able to do all that is required of them. In some instances which have come under our notice, apprentices after they have served their time, have been kept on as improvers at a few shillings a week, and perform the duties of receptionists. We are now, of course, speaking of females, though the same frequently applies to males. In this way labour is obtained at a cheap rate by some. The question arises, When does a person cease to be an improver? We of course mean When should he no longer be expected to work at an improver's salary? It is fully realised that with extended experience everyone should constantly be an improver, but that is not the point we are discussing. It would be interesting to ascertain the views of some proprietors of photographic studios as to the precise point at which an "improver" ceases to be such and becomes a full-fledged craftsman. We recently read an advertisement to the following effect:—"Vacancy for gentleman improver at operating and retouching; must have had at least 5 or 6 years' first-class practical experience in studio work; those who can work up and colour preferred; only first-class, smart assistants need apply. . . . State lowest salary." The italics are ours. One would have surmised that any gentleman who had had five or six years' first-class practical experience in studio work would scarcely look upon himself as an improver, yet it would be interesting to know the maximum salary which would be entertained from these "improver" applicants.

#### THE SIGNATURE.

The photographer's name, appearing as it does upon every photograph turned out, and also upon his stationery and his advertisements, is to him a trade-mark, and every effort should be put forth to evolve a signature at once dignified and distinctive, so that the public will, unconsciously perhaps, remember it. If the reader has not been blessed with a name striking in itself, it is the more important that its printed form should be forceful and characteristic. If the photographer's name, either on advertisement matter or stationery, appears in ordinary unnoticeable type, an opportunity of making the name and work more easily recalled is lost.

Many well-known photographers, whom one will easily call to mind, have been provided, either by accident of birth or business foresight, with names which, owing to their peculiarities, make a lasting impression on the observer. Others, however, are only able to lay claim to cognomens of the Smith, Jones, and Robinson variety, and these have to put their names repeatedly before the public in a striking way if they are to be naturally associated with them and not with other business men in the same town. We all know "Boots," cash chemists; how that last phrase is inseparably associated with the name. This connection of a signature and explanatory phrase might be adopted by some photographers.

When designing the signature one has to decide between

a facsimile signature or the very clear even ones obtained from the block-makers when a facsimile signature is not stipulated for. When making the draft one's own particular calligraphy must be kept in mind, for it is advisable to have the name on one's letterheads and the signature at the foot fairly similar, an idea of unity being thus created. If one's usual signature does not lend itself well to the idea, very little practice would enable one to alter it to suit the block; but in this case warn the bank.

The sketch, if not for a facsimile block, need not have the perfect appearance one associates with an ordinary cut block, for the carver will round it up and finish it off, so long as he has the idea. A few minutes experimenting with a pen and a glance through the advertisement portion of a magazine will soon enable you to evolve something particularly suitable for one's own name; but do not be in too much of a hurry, for, once chosen, the form should never be altered or deviated from in any way. With the aid of a "J" pen or a quill some handsome results are obtainable, and of such a nature as to show up strongly amongst ordinary letterpress. One most distinctive feature of a good sign manual is the flourish or underlining. It may be either a continuation of last letter curved and drawn back, or a more uncommon method is possible in the case of some capitals when they can be made to supply the line. A, for instance, would have the right-hand leg curved and extended under the word. A stroke entirely separated from the word may be used, in which case it will be preferably thick and heavy. In any case, it should resemble the natural stroke of a pen.

Presupposing that a block of the required description has been obtained, either line for newspaper, relief for stationery headings and folders, or sunk for stiff mounts, its position must be decided upon, though there is plenty of latitude in the matter. Probably the mount is the most important recipient of our names, and the position for stamping depends upon the plate-mark and print. Either the right or left hand side under the space for photograph is usual, but when ordering mounts specify the exact place you fancy, for it may easily enhance and balance up the mount. Should your prints be enclosed in

cover, a good place for name in harmonising colour blend, blocked, is near the edge of front and rather above the centre. The stationery can be made very smart and careful design. A plain line block printed with other matter is cheap, but not nearly such good style as the impression in colour from a relief block. Be careful to make the heading too showy; a simple arrangement type well balanced with the name only standing out is far better than a large name printed in type dead in centre page with a lot of ornamented type rules and printer's ornaments pulled round it.

Some firms with a very exclusive clientèle affect ordinary note-paper of superfine quality for their correspondence, etc.; it is a moot point as to whether the name as well as the address should appear upon it. An unbusinesslike appearance is engendered without it, whilst the professional style is to a small extent lost if it is included. In any case the signature, if used on this class of paper, must be kept small, and preferably plain stamped. A very good position for it is to have address as usual and print name across the left hand top corner. The name may be used on envelopes for ordinary correspondence, but it is more dignified if placed unobtrusively on the flap. Under no circumstances should wrappers enclosing advertising matter be provided with the tell-tale mark of the place of origin.

The signature should be upon stick-on labels, but should not be elaborate. Placed simply in one corner without rulings or ornament of any kind, the reputation of the firm will not be reflected upon. One must remember that photography must be unconfounded with the less refined trades, and the idea of its position is best given by the taste displayed in everything connected with it. Simplicity and lack of symmetry will generally achieve our aim.

It will be obvious that the more people that are familiarised with a name, and connect a certain form of the name inseparably with it the better for the business. For this reason the line block should always be used for the advertisements, as being different from and more striking than names set in ordinary caps. It is astonishing how a signature block stands out and catches the eye amongst the page of letterpress, as a look at the newspaper will prove.

## PORTRAITURE—ANCIENT AND MODERN.

Frederick Hollyer's Exhibition of Portraiture at his studios, 9, Pembroke Square, Kensington, W., remains open until November 5.

It is not too much to say that this highly interesting show of work is in one respect unique. It gives, in photographic medium, portraits of men and women that in the ordinary way do not hang side by side on an exhibition wall. It most resembles the National Portrait Gallery in its make up; only there technical excellence is not the prime consideration, whilst at 9, Pembroke Square the technical aspect is, like Cæsar's wife, above suspicion. From Geoffrey Chaucer to Mr. John L. Sargent, R.A., is a far cry; but that wide historic range is the very thing that makes the exhibition so positively moving in its interest. To a literary man, it must be a perfect feast; to the archaeologist a mine of wealth.

### The Mantle of the Mezzotinter.

Of course, it is quite unnecessary to say that this harvest of faces, gathered from fields through which Time long since left his footprints, is made possible by Mr. Hollyer's life-long work of reproducing the portraiture of past ages. He has stepped in where the mezzotinter stepped out; and although it would be idle to affirm that a platinum or carbon print, however beautiful, can rival the best work of the mezzotinter's art, yet in one respect it may be thought preferable as a

reproduction, namely, in that the photograph is a facsimile in the matter of details, markings, and even of blemishes, which they inherent or acquired. The mezzotinter re-drew, and that process opened the door for all kinds of variation from the original, which to-day must necessarily discount his records as reliable documents. But on the score of beauty merely it is fair to say that Mr. Hollyer's prints, leaving the peculiar velvety quality of the mezzotint out of account, are as covetable as the costly reproductions of a century ago. And they cost but a few shillings apiece!

### Old Masters.

The exhibition is admirably arranged in the cosy room of the old Kensington house, where father and son carried forward their delightful occupations. A chronological order is approximately preserved, and by the guidance of this the progress of portrait painting through the ages is most instructively marked for the visitor. The poet Chaucer leads off, and fitly introduces a company of Italian gentlemen, just as he did six centuries ago in his writings. Ironically enough, however, Savonarola comes next—Time is a leveller, and Mr. Hollyer here lends a hand. There are naturally several

ings of the National Gallery, such as that lovable old by Bellini, and Sarto's portrait of himself. Next we upon the Holbein drawings at Windsor, those stupendous draughtsmanship, at once "nervous" and dead. An amateur photographer once asserted in the Press that "Holbein and Dürer could not draw!" Next are three by Lasquez, for whose supremacy in tone values the reduction by photography affords an enduring testimony. To the four Vandykes, there are no works more delightfully in the gallery. Every photographer in the kingdom should buy copies of these two graceful and accomplished portraits, and hang them, suitably framed, in his studio (not the reception room), as ideals in his craft. That palpitating portrait of Rubens, the "Chapeau de Poile" is perhaps a little too silvery in effect to render the strong colour scheme the original; but there is no loss of the fascinating charm of this full-blooded lady exerts, in whose breast abandon she strives with propriety.

### Old Friends.

Shakespeare, John Knox, Isaac Walton, Bunyan, Milton, Howell, Pepys, looking like a boy, and Cowley, looking like a girl, with Waller between them, looking like a roué—truly a goodly company. We follow the flight of ages, and find Lord Chesterfield, Smollett, Swift, and his "Stella," Pope, and Keats, the latter a particularly rich print, because it happens to be from a mezzotint after Reynolds. Three portraits of the Siddons are here, by Beechey, Lawrence, and another; strangely enough, neither Gainsborough's nor Reynolds's. The great Madame de Pompadour, by Boucher, is more distinctive in the little version here than it is in the original. The hard blue of the dress and the general coldness of colour are distinctly unsympathetic. But it is a fact that reproduction by photography is the making of many an old friend. Two of Johnson and one of Goldsmith swell this lengthy line of notables, which includes artists, statesmen, court beauties, and kings, besides the men of letters. The latter, however, far outnumber the others, and they gain increased value from the fact that they appear in several versions according to different artists. To enumerate them would be simply to write a list of famous names. They are their interest for the photographer when they occur near our own times as to fall into the period of the

photographic era. We then see how the camera tells, not as a reproductive but as a creative agent.

### Where the Camera Scores.

In the case of John Ruskin, we get from Mr. Hollier a far stronger physiognomy than the painters have given. He shows a profile bold and grand, with a fine sweep of beard that leads the eye down to the sensitive hands. This leonine head belongs, of course, to Ruskin's last days, when an occasional snarl in a newspaper was all that the world knew of the former voluminous writer of rhapsodical elegancies. Watts's portrait of himself in the prime of life should be placed in the National Gallery amongst the great Italians; it would not suffer, as the reproduction here reminds us; but it is the Watts of Mr. Hollier's front view which gives intimately the painter-prophet that the world reveres. Similarly, the photographer scores with George Meredith, Hollier's well-known profile of whom is infinitely to be preferred as a likeness of the actual man to the picture by Watts himself, which is but a fine dream of Meredith.

Getting near to the end of the exhibition, and leaving the series of Tennyson and Carlyle, which is of absorbing interest, we come to the present generation with Leighton, Browning, Morris, Rossetti, and others of the same standing. Professor Huxley and Charles Darwin are among them.

Being invited to ascend a staircase, I found there another assemblage of celebrities, among whom was my old friend Fredk. H. Evans, disporting in the company of Mrs. Patrick Campbell and the Rev. Stopford Brooke.

### A Good Idea.

It has recently been suggested that the National Portrait Gallery should augment its records and fill up its gaps by acquiring photographs of this kind. Never was a better idea mooted. A man of such a widely embracing circle of acquaintances as Mr. Hollier should be an inexhaustible mine to the promoters of a gallery of portraits. In many respects the photographic portrait is a truer document than the painted one, and Mr. Hollier has scores of portfolios of them. When he chooses to take his well-earned rest from his long labours, his son is there, artistic and energetic, ready to carry on the work alone in the path of well-proved traditions.

F. C. TILNEY.

## FOREIGN NOTES AND NEWS.

### Reversed Negatives.

Zima strongly recommends, in the current number of the *photographische Korrespondenz*, the following method of making reversed negatives:—A well-cleaned sheet of glass should be rubbed with a 0.5 per cent. solution of silicate of potash and then coated with a 2 per cent. solution of gelatine, preferably hard collotype gelatine, and dried. It should then be sensitised in a 2 per cent. solution of ammonium bichromate and dried. It is then to be exposed under the negative, the duration of exposure being controlled by a photometer, in which should be used a strip of gelatine paper, sensitised in the above bath. After exposure the plate should be well washed in running water till the film is free of colour, and to remove the reduced chromium salt it can be immersed in a very dilute acid sulphite solution or a 2 per cent. solution of metabisulphite of potash. The plate should then be immersed in a solution of platinschwarz M, a dye made by Meister, Loeb and Brünig. This dye only stains the unhardened gelatine of the negative is thus obtained, which is absolutely free from colour. This process should be particularly useful for collotype and lantern workers. If a transparency be used the result will, of course, be a transparency, and as bright and dark blue, green, and brown are obtainable, this process will be a welcome method for making lantern slides, for the latter, possessing no grain, show very well on the screen.

### Filtration of Colloids.

Since recent researches, notably those of Steintopf and Szigmondy, the inventors of the "ultramicroscope," have taught us that colloidal solutions are of the nature of suspension of particles—ultramicroscopic in size—in a non-colloidal fluid, it appeared reasonable to conceive that filtering media might be found that would strain off these exceedingly minute particles from the fluid in which they floated, or rather some of them, so as to fractionate the colloids into different portions according to the several degrees of fineness of the filters employed. The task of constructing such filters has been taken in hand by Dr. Bechhold, of Frankfurt-on-Main, with a considerable measure of success. According to the report of the Stuttgart Conference, in the "British and Colonial Druggist," using paper and other tissues impregnated with jellies of several degrees of concentration, and submitting the colloidal fluids to a pressure of 0.2 to 0.4 atmosphere, he has effected separations of various kinds, both inorganic and organic colloids being tested; of the former, arsenious sulphide and ferric hydrate are mentioned. He has concentrated albumin and hæmoglobin—the filtrate being free from albumenoid—globulin has been separated from the sodium chloride which dissolved it. Particularly significant is the behaviour of ferments and toxins under the new filtering test; while ordinary albuminoid bodies proved to be tolerably "indifferent" towards the filtering medium—i.e., they did not interact, the toxins and ferments showed a tendency to combine

or "dye" it, this expression being employed to denote a process of fixing akin to that of a dye upon a fabric but without colour; hence he calls toxins and ferments "colourless dyestuffs." The author emphasises the importance of the new principle to the investigation of the sizes of colloidal particles, and there are numerous problems in biological and medical chemistry to the resolution of which it should render valuable aid.

### Keeping Emulsions in Jelly Form.

Dr. Homolka summarises the various methods of keeping emulsions in jelly form, and states that far preferable to any is the use of pure benzole. The melted emulsion should be poured into a large stoppered bottle or vessel, and placed in ice so as to set it quickly, and stirred so as to prevent the bromide settling out. When thoroughly hard, a thin film of pure benzole should be poured on the top of the emulsion and the vessel closed and placed in an ice chest. When required for use the benzole should be poured off, and the last traces allowed to spontaneously evaporate, and then the emulsion melted, as usual. Dr. Homolka states that he has kept even extremely rapid emulsions by this method.

### The Lippmann Process.

Dr. Lehmann, in Eder's "Jahrbuch," states that all processes hitherto given for sensitising the emulsion for this process are based on an accurate proportion of the dyes, so that without a filter compound colours could be correctly rendered. Abandoning this method, the dyes are added in such quantities that each exerts its maximum action, and Dr. Lehmann uses a compensating filter, which enables all colours and even pure whites to be obtained. For the filter three stock solutions are required:—

1. Cyanine .....	0.4 gms.
Alcohol .....	200 ccs.
To be dissolved cold.	
2. Erythrosine .....	0.4 gms.
Alcohol .....	200 ccs.
To be dissolved cold.	

3. Aesculine .....	0.4 gms.
Hot distilled water .....	10 ccs.
When dissolved add:—	
Alcohol .....	190 ccs.
Ammonia, sp. gr. 0.91 .....	3 drops.

To make the filter, stock solutions Nos. 1 and 2 must be diluted with 30 parts of water or alcohol. The actual filter which is used in 5 mm. width is:

No. 1 solution (1:30) .....	2½ parts.
No. 2 solution (1:30) .....	5 parts.
No. 3 solution undiluted .....	1 part.
Alcohol or water .....	1½ parts

This solution must be kept in the dark, as the cyanine bleaches in light. A useful substitute for the cyanine has not yet been found, though the following filter is the nearest:—

Methyl violet (1:15000) .....	0.6
Erythrosine (1:15000) .....	2.5
Aesculine (1:500) .....	1.0
Alcohol .....	7.0

The above is a brief extract from a book, "Beiträge zur Theorie und Praxis der direkten Farben-Photographie mittels stehender Wellen nach Lippmann's Verfahren," by Dr. Lehmann, which is shortly to be published.

### The Young-Helmholtz Theory and Three-Colour Photography.

Dr. Pfandler, of Graz, in order to explain the above theory, compares the seven spectrum colours to seven bells, and gives them various numerical values, and shows by tables that the sum of the sounds caused by ringing the bells in sets of three may be likened to the fundamental colour sensations, red, green, and blue-violet. He states that A. König has proved that the eye can recognise about 160 tints in the spectrum, and as the diameter of the smallest sensitive surface of the retina is 0.004 mm., it is impossible that 160 nerve fibrils can be fastened to such a small area, and therefore the division of these tints into several groups of different strengths is the most satisfactory and economical solution of the problem. The author concludes by stating that a study of the curves of König and Deterici are of extreme importance in colour photography, and it is only by obtaining plates or filters which shall have similar overlapping curves that a reproduction of compound colours true to nature can be obtained.

### A Simple Photometer.

Dr. Stolze suggests the use of two right-angled prisms  $cd$  and  $cf$ , fastened to a thin sheet of opal glass. Assuming the sources to be at  $a$  and  $b$ , the prisms have only to be shifted right or left till the illumination is even, and then measure

Fig. 1.

tances,  $ac$  and  $bc$ , then the intensities of the lights will be  $a^2 : b^2$ . This arrangement can obviously also be used to compare the actinic power of the two lights.

### Silver Phosphate Print-out Emulsions.

Professor Valenta gives the following method of making the

Raw collodion (3 to 3.5 per cent.) .....	1,500 ccs.
Phosphoric acid (20 per cent.) .....	20 ccs.
Citric acid .....	60 ccs.
Alcohol .....	100 ccs.

Dissolve the acids in the alcohol and add to the collodion. add:

Silver nitrate, powdered .....	60-80 gms.
Liq. ammonia .....	q.s.
Warm alcohol .....	250 ccs.

The ammonia should be added gradually to the powdered silver nitrate till a perfectly clear solution is obtained, and then the alcohol added to the emulsion after this addition should be added:

Ether .....	250 ccs.
the whole filtered through cotton wool and then	
Glycerine .....	10 ccs.
Alcohol .....	10 ccs.

added. This gives brilliant prints, which can be either printed out and toned in the usual way or else faintly printed and developed with an acid metol developer. The tones obtained by the process are rich brownish blacks, with pure whites.

### Developing Platinotypes.

Dr. Jacoby states that the following developer will give blacks with absolutely pure whites on ordinary black tone platinotype paper:—

Potassium oxalate .....	250 parts.
Zinc oxalate .....	100 parts.
Water .....	1,000 parts.

Heat to 77 deg. Fahr. If the colour obtained is too warm zinc oxalate should be used. To obtain sepia tones, he recommends the use of ammonium monophosphate,  $NH_4$ ,  $H_2$ ,  $PO_4$ , with a cupric sulphate.

Potassium oxalate .....	200 parts.
Ammonium monophosphate .....	50 parts.
Cupric sulphate .....	2 parts.
Water .....	1,000 parts.

The prints should remain in this developer at least five minutes.

### A New High-light Reducer.

Dr. Lüppo-Cramer states that a mixture—

Nitric acid .....	50 ccs.
Water .....	30 ccs.
Ammonium sulphocyanide 20 p.c. sol. .....	20 ccs.

—will reduce the high lights of a negative exactly in the same way as ammonium persulphate. The action is rather slow, and it is advisable to immerse the negative before treatment in a 2 per cent. solution of chrome alum and dry. On the other hand, he states that a mixture of a 5 per cent. acidulated solution of ammonium persulphate with 2 per cent. solution of ammonium sulphocyanide like Farmer's reducer, and attacks the shadows first.

### Coloured Illuminants for Three-Colour Work.

W. Gamble states, in Eder's "Jahrbuch," that the exposure can be considerably reduced if an original be illuminated with the necessary coloured light instead of using filters, and that he has devised

patented an electric lamp, in which are two carbons, which can be alternately brought into play. The one gives an orange red light and the other the ordinary violet of the enclosed arc. So far he has not been able to obtain green illumination, though there should be no difficulty in this, considering the number of chemicals which

give green lights. The exposure with the orange red carbons is 50 per cent. less than that of the open or enclosed ordinary carbons. The lamp is constructed by Penrose and Co.. The author disclaims any originality in the idea, and states that Warnerke recommended coloured illumination many years ago, in a paper before the R.P.S.

## DOUBLE CARBONATES AS DEVELOPERS.

### I.

In the articles entitled "Development with the Alkaline Carbonates," which appeared in the numbers of this JOURNAL for August 5 and 21 and September 28, 1894, I gave some account of the ordinary carbonate developers in every-day use, and attempted at the same time, from data obtained experimentally, to classify these according to their properties, with the object of exhibiting the special character of each.

Among the developers which thus received attention, particular reference was made to the pyrogallol-ammonium sesquicarbonate bath, a re-agent which, as I showed in my summary of results by a comparison of its merits and defects with those of the other carbonate baths described, was found to possess qualities of a high order and of no little practical importance and utility. Having afterwards made a careful and special study of the properties of the developer in question, I gave a full account of my investigations in Volume XLII. of the JOURNAL, in the numbers for March 1 and May 6 and 10, 1895. These latter papers, in view of the facts elicited, attracted a considerable amount of notice, and gave rise to an interesting discussion, in which the late Mr. W. B. Bolton and other leading photographic authorities took part.

In the autumn of the same year I made some further experiments with this developer, these having been undertaken chiefly with the object of finding a means of improving the keeping qualities of the aqueous solution of the ammonium salt. Whilst so engaged, the idea suggested itself to me that the stability of the developer might be increased by substituting for the simple sesquicarbonate a double carbonate containing the same base in the form of one of its numerous compounds with the heavy metals. I decided then and thereupon to test whether such was the case, and accordingly selected the double carbonate of copper and ammonium as a suitable salt for the preliminary trial.

A slight difficulty of a practical nature here, however, interposed itself. In order to prepare the double carbonate, copper carbonate must first be obtained. But the so-called carbonate, as usually prepared—by precipitation—is, as is well known, not the pure salt, but a mixture of carbonate and hydrate in variable proportions. Instead, therefore, of attempting to prepare the double salt by precipitating the copper in this dubious form, and dissolving the mixture of compounds in a solution of the sesquicarbonate, I thought it better to avail myself of a valuable property which that re-agent, in virtue of its acidific character, possesses, viz., of acting as a solvent of metallic bases.

Ammonium sesquicarbonate, as I may remind my readers, possesses a chemical constitution expressed by the formula  $(\text{NH}_4)_2\text{H}_2(\text{CO}_3)_3$ . When, however, the salt is dissolved in water, it is decomposed, and converted into two new compounds, viz., the neutral carbonate  $\text{NH}_4\text{CO}_3$ , and the hydrogen carbonate,  $\text{NH}_4\text{HCO}_3$ .

The change which the sesquicarbonate undergoes on solution is represented by the chemical equation here given:—

$(\text{NH}_4)_2\text{H}_2(\text{CO}_3)_3 + \text{aq.} = (\text{NH}_4)_2\text{CO}_3 + 2\text{NH}_4\text{HCO}_3 + \text{aq.}$   
The hydrogen carbonate thus produced possesses properties of an acid character, and is found, among other things, to dissolve metallic oxides and hydrates, there being formed in every such case a double carbonate of ammonium and the particular metal employed.

In order to prepare my stock developing solution of the double carbonate of ammonium and copper I dissolved, in the first place, 51 grains of crystallised ammonium sesquicarbonate in four fluid ounces of water. I then added to the solution thus obtained 40 grains of cupric oxide, and, after stirring, set the two aside to digest together for a week, during the whole of which time the contents of the flask containing the mixture were freely exposed to the air.

The clear, colourless supernatant liquor gradually assumed, on standing, a rich, deep blue colour. At the expiry of the week I filtered off the blue solution from the black insoluble residue. The latter, after washing and drying, was found to weigh exactly 32 grains. Eight grains of cupric oxide had, therefore, been dissolved by the ammoniacal solution. The formula of the stock developer as prepared by this process was thus:—

Ammonium sesquicarbonate .....	12.75 grains.
Cupric oxide .....	2 grains.
Water .....	1 fluid ounce.

This stock solution was made up for use during the week September 11 to 18, 1895.

For the purpose of testing the developing properties of the copper bath, I exposed, a few days afterwards, during bright sunshine at mid-day, a slow gelatino-bromide plate on a landscape subject, the stop used on the occasion being  $f/14$ , and the exposure given, four seconds. To develop, I prepared a second aqueous solution of ammonium sesquicarbonate of the strength of 12.75 grains per fluid ounce. To this I then added an equal volume of the stock copper-ammonium carbonate solution, and to each fluid ounce of the mixed solutions 2.25 grains of pyrogallol and half a grain of potassium bromide.

The plate exposed as above was immersed in the bath for development. After nine minutes had elapsed the first faint outlines of the image began to appear, these being visible when the film was viewed by transmitted light. The subsequent growth in density was very tardy and gradual on account of the abnormally slow action of the copper solution, and it was not, indeed, actually until seventy minutes had elapsed from the start of the developing operations that the image had acquired a degree of vigour sufficient to justify the removal of the plate from the bath. After a brief washing in water, the picture was transferred to the usual thiosulphate bath, from which, on the completion of fixing, it was removed to the washing trough.

The finished negative so produced was of striking beauty and excellence, and in certain respects presented an appearance altogether unique. The colour of the image was an orange-pink of singular brilliancy and richness, resembling in its lighter shades the hue of pure burnished copper, or that of the freshly-prepared suboxide of the same metal, and inclining in its darker tints towards an agreeable ferruginous or ochre red. The gradation of tone obtained with the developer was of the utmost delicacy, whilst the density of the image, alike in its highest lights and in the deepest shadows of the subject, was as nearly perfect as could well be imagined.

A very interesting optical peculiarity of the picture was its uncommon sharpness of focus, which was such that the minutest details, and even those lying in different planes, were reproduced with a microscopic fidelity of effect truly remarkable. The image, in point of fact, much resembled in its pictorial qualities the best class of work produced by means of the wet-plate collodion process, and bore little or no likeness to a gelatino-bromide negative of the ordinary type.

In the course of further experiment it was conclusively shown that this variation in the appearance of the image must be attributed to the chemical action of the copper solution. With the view of settling this point, several dry-plates from the same batch as that already used were exposed on the same subject under like physical and optical conditions. These were then treated in a pyrogallol developer in which dilute ammonia was substituted for the copper-ammonium carbonate solution. In no case, it was found, did the resulting image exhibit the peculiar qualities of tone and focus which

characterised the negative obtained in the manner above described. On closely examining the film of the latter, directly after the removal of the plate from the copper-bath, it had been noticed that through the action of the developer the pores of the gelatine had undergone contraction, the change being rendered apparent by a marked increase in the smoothness and tenacity of the colloid surface. An important practical consequence of this change of physical state was that the film was found to have acquired a degree of toughness so considerable as to permit of the process of washing before and after fixing being carried out without the usual risk of frilling or abrasion. It seems exceedingly likely, also, that to this contraction produced by the action of the copper bath on the gelatine vehicle should be assigned the special sharpness of focus to which I have above referred as such a noticeable feature of the finished negative.

Several prints on gelatino-chloride paper were afterwards taken from the negative, which were greatly admired for their unusual delicacy and softness of effect. The printing of these, on account of the pronounced non-actinic qualities of the image, was a somewhat lengthy and tedious operation.

The success of the experiment with the copper-ammonium carbonate bath was regarded as specially interesting and important, as serving to demonstrate the practicability, and, under certain conditions, desirability, of employing a solution of a double carbonate as a substitute for the ordinary carbonate bath in development. It was thought advantageous, therefore, to investigate the matter further, and, in particular, to experiment with the object of finding whether other salts of the double carbonate class were suitable for use in this description of photographic work. It was not, however, until the month of August, 1905, that the proposed inquiry was proceeded with.

Of the various double carbonates then examined a considerable number were rejected as unsuitable for developing purposes. The majority of these were compounds regarded as objectionable only on the score of their insolubility or very limited solubility in water. Of the remainder, several were deemed unfit for use as developers by reason of the fact that their aqueous solutions were found to be precipitated on the addition of pyrogallol, whilst a third class of these salts—of which argentic-ammonium carbonate may be cited as an instance—could not be employed in the manner proposed, owing to their deleterious action on the gelatine film.

The carbonates finally selected—excluding, however, from the present enumeration copper-ammonium carbonate, which was also included in the list of serviceable photographic re-agents—were five in number, viz., those of cobalt-ammonium, nickel-ammonium, zinc-ammonium, magnesium-ammonium, and uranium-ammonium.

These compounds were prepared for experimental purposes by precipitating by the addition of a suitable carbonate, aqueous solutions of salts of the respective metals required, washing the insoluble carbonates so obtained, and thereafter dissolving the precipitates in a solution of ammonium sesquicarbonate.

For the preparation of the cobalt-ammonium carbonate developing bath, thirty minims of a saturated aqueous solution of cobaltous nitrate were diluted with three or four times their own volume of water. A solution of sodium carbonate was next made up of the strength of 100 grains of the common crystallised salt ( $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ ) to each fluid ounce of water. Part of this solution was then added gradually to the first, the addition being carried a little beyond the stage at which the last of the cobalt was seen to be precipitated in the form of carbonate. The curdy violet precipitate so obtained was allowed to settle, after which it was thoroughly washed by decantation in repeated changes of water. The washing having been completed and the bulk of the residual water withdrawn by means of a syphon, three fluid ounces of an aqueous solution of ammonium sesquicarbonate of the strength of 12.5 grains of the crystallised salt per ounce were added to the flask containing the moist precipitate. The contents of the flask were well shaken at intervals during the next forty-eight hours, the result being that about two-thirds of the precipitate were dissolved, and a fine crimson solution of the double carbonate was produced. The undissolved portion of the precipitate was allowed to digest in this solution for five months. An additional ounce of the ammonium sesquicarbonate solution was then added, the addition being made a few days before the bath was employed for development, and the

flask was again well shaken and set aside. When the bath was required for use the insoluble matter that still remained after the second digestion was removed by filtration.

The nickel-ammonium carbonate bath was prepared in the following manner. Ten grains of hydrated nickel sulphate ( $\text{NiSO}_4 \cdot 7\text{H}_2\text{O}$ ) having been dissolved in water, sodium carbonate solution was, before, added in slight excess to effect the precipitation of the metal. The vessel was then allowed to stand for a few hours until the pale green precipitate formed had completely subsided, after which the soluble products of the decomposition were withdrawn by decantation, and washing was proceeded with until the last trace of these impurities had been removed. The water was then drained off, and a solution of ammonium-sesquicarbonate (37.5 grains of the salt in two fluid ounces of water) was added to act as a solvent of the nickel compound. On shaking the flask, nearly all the precipitate dissolved, there being formed a rich blue-green solution of the double-salt.

A few drops of the green liquid were withdrawn and tested with an alcoholic solution of pyrogallol. A precipitate was instantly formed, of an intense purple-black colour. On adding thereto a little of an aqueous solution of sodium sulphite, the precipitate was dissolved and a solution of a dirty-grey colour was obtained.

In view of the facts just mentioned, there appeared a necessity for the addition of sodium sulphite to the stock nickel bath in order to prevent the formation of a precipitate during the operations of development, and 75 grains of the crystallised salt were accordingly dissolved in one fluid ounce of water, and added to the stock developer a few days before this was required for use.

To prepare the zinc-ammonium carbonate bath, 50 grains of chloride of zinc were dissolved in half an ounce of water, and the zinc was duly precipitated in the form of basic carbonate, a solution of sodium carbonate being again employed to effect the decomposition. The white flocculent precipitate which resulted was washed by decantation in the usual way, and after the removal of the bulk of the water was treated with an aqueous solution of ammonium sesquicarbonate of the strength of 12.5 grains per fluid ounce. The flask was well shaken and set aside to digest. When five months had elapsed, and immediately before the bath was required for development, the contents were filtered to remove from the saturated solution the undissolved residue of basic carbonate that still remained.

In making up the magnesium-ammonium bath a different system of procedure was adopted. Eighteen grains of hydrated magnesium sulphate ( $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ ) were dissolved in water, and from the solution thus obtained the magnesium was then precipitated in the form of hydrate by the addition of an excess of strong ammonia. The precipitate was washed by decantation as usual, after which it was dissolved by the aid of a gentle heat in a weak solution of citric acid made up to the volume of one fluid ounce and containing 15 grains of the crystallised acid. After cooling, 25 grains of ammonium-sesquicarbonate, previously dissolved in one ounce of water, were added to the newly-formed solution. A slight effervescence ensued, which was due to the partial decomposition of the carbonate by a small residue of acid that had hitherto escaped neutralisation.

The last of these stock developers, the uranium-ammonium carbonate bath, was made up for use by adding gradually to a concentrated solution of uranium nitrate, containing 7 grains of the crystallised salt, two fluid ounces of an aqueous solution of ammonium-sesquicarbonate of the usual strength. As the yellow precipitate that was formed on the addition of the carbonate speedily re-dissolved, the double salt could not be purified by decantation and subsequent washing in the ordinary way. The bath, accordingly, as prepared for use, contained as a by-product a considerable percentage of ammonium nitrate, a constituent which, however, as will hereafter be shown, did not appear to impair its developing properties in any marked degree.

For restraining purposes, eight grains of potassium bromide were dissolved in an ounce of water, and this stock solution, which was added, usually, in one-grain doses to the developer, was employed as circumstances demanded.

A concentrated stock solution of pyrogallol in alcohol and glycerine was used in the developing operations. Of these I propose to give a particular account in my next paper.

MATTHEW WILSON.

THE MERCURY-VAPOUR LAMP.

In the current number of the "Journal of the Franklin Institute" there appears a fairly exhaustive paper, by Dr. Weintraub, on the mercury arc, from which the following notes are extracted.

The structure of the mercury arc shows a positive column proceeding from the anode and a relatively dark cathode space exactly as seen in any Geisler tube; there is also a cathode spot which is always in irregular motion over the face of the cathode. If the mercury vapour pressure gets above certain value the positive column does fill the entire section of the tube, but concentrates itself in the middle, and is surrounded by a space of relatively equal luminosity.

The formation of the arc in the vapours of other metals, such as potassium, sodium, lithium bismuth, lead, zinc, cadmium, and their alloys, and as amalgams has not, unfortunately, lead to any satisfactory results, as the amount of light is small and the efficiency small. The methods attempted for improving the quality of the light were as follows:—(a) The use of ordinary incandescent lamps in series with the mercury arc. The General Electric Company, U.S.A., has developed the so-called orthochromatic mercury arc lamp, in which a number of incandescent lamps in multiple are placed in series with the mercury arc, the incandescent lamps burning at a normal efficiency. The whole is enclosed in a holophane globe, which serves the purpose of blending the two lights of different colours. This system has, of course, a lower efficiency than the mercury arc alone, and also leads to somewhat larger units.

(b) The use of amalgams of the alkali metals and of the metals of the alkali earths.—By adding metals like potassium, sodium, lithium, calcium, etc., to the mercury, the spectrum of the arc can be changed. The practical application for the purpose of improving the colour of the mercury arc meets, however, with considerable difficulties and disadvantages of which I mention the attack on the glass by the alkali metals, the lowering of the efficiency, etc.

(c) Use of fluorescent bodies which have the property of transforming the violet and green rays into those nearer the red end of the spectrum.—Unfortunately none of the substances known possess

this property in a degree sufficient for practical purposes; also this transformation is very wasteful.

(d) Change of the nature of the discharge through the mercury vapours.—The spectrum of the light emitted by the discharge through vapours or gasses depends on the nature of the discharge. Work in this direction for the purpose of improving the colour of the mercury arc has given promising results. One of the experiments, showing the essentials of the phenomenon, is illustrated in the sketch.

T is a transformer of not too small a capacity, C condensers, h a small inductance; AB is a direct current arc which supplies ionised vapour, this ionised vapour filling the space between the two other electrodes, E and D. Under proper conditions the discharge of the condenser between the electrodes E and D has a spectrum rich in red rays, the arc ED giving a brilliant white light.

MR. J. T. SANDELL—AN APPEAL.

Since the appearance of the list of donations last week the following has been sent to us in response to the appeal of Messrs. T. K. Grant and J. B. B. Wellington:—

E. J. Wall .....	£ s. d.
E. G. Richardson .....	10 6
	10 6

The following sums have also been subscribed:—

J. T. Chapman .....	£ s. d.
W. Hughes .....	1 1 0
Croydon Camera Club (1st donation per W. H. Smith, President) .....	1 1 0
G. W. W. ....	5 10 0
S. H. Wratten .....	1 1 0
F. C. L. Wratten .....	1 1 0
Devonport Camera Club (per A. J. Catford).....	5 5 0
Sir J. W. Swan .....	1 1 0
W. A. Vinden .....	5 5 0
Amount already acknowledged .....	1 0 0
	75 14 6

Total ..... 99 0 6

The response from the two photographic societies named above represents, we understand, the interest at present shown by the three or four hundred societies in the kingdom, very many of whom have been indebted to Mr. Sandell for demonstrations. We hope that the example of Croydon and Devonport will not be disregarded by the majority of associations in the country. Many no doubt will be influenced by the action of the larger bodies in Birmingham, Manchester, Liverpool, Leeds, and Glasgow and Edinburgh. We hope this reminder of the appeal already made by Mr. T. K. Grant will meet the eyes of the officers in these centres.

THE SOCIETY OF COLOUR PHOTOGRAPHERS.

The Committee appointed by the preliminary meeting of the above Society held on the 16th inst., have drawn up the following code of rules and working propaganda, which will be placed before a General Meeting of Members for confirmation, on November 14th.

RULES.

- (1) *Title*.—The Society shall be called "The Society of Colour Photographers."
- (2) *Objects*.—The objects of the Society shall be to further the progress of Colour Photography.
- (3) *Membership*.—All interested in Colour Photography are eligible for Membership.
- (4) *Nomination*.—Ladies and Gentlemen may be admitted to Membership on the nomination of a Member, or upon their own application. The Committee shall decide any question as to eligibility.
- (5) *Subscription*.—The subscription shall be 5s. per annum, payable on admission. Subsequent subscriptions shall be payable in advance on the 1st of January in each year. The subscriptions of Members joining after October 1st shall be considered as paid up for the following year.

No Member shall be entitled to any of the privileges of Membership if their subscription shall be three months in arrear.

(6) *Meetings*.—Ordinary meetings shall be held from time to time, fourteen days' notice of which shall be given by the Hon. Secretary. The Committee may call extraordinary meetings as they may think advisable. At each Annual General Meeting, which shall be held in October in each year, a balance sheet shall be presented, and Officers elected, and any other business that may require the decision of a General Meeting. Special General Meetings shall be called within fourteen days of the receipt by the Hon. Secretary of a requisition

signed by five Members, stating the purpose of the Meeting, and no subject shall be discussed thereat but for which the Meeting was called.

(7) *Alteration of Rules.*—Alterations of the rules of the Society shall only be made at the Annual General Meeting or a Special General Meeting. The alterations proposed shall be stated in the notice convening the Meeting.

(8) *Officers.*—The Officers of the Society shall be a Committee of four Members, a Treasurer and Secretary. The Officers shall retire annually, but shall be eligible for re-election.

(9) *Books of Accounts.*—Proper books of accounts shall be kept by the Treasurer, and a book of minutes shall be kept by the Hon. Secretary.

(10) The payment of a subscription by a member shall be taken as indicating acquiescence in these rules.

The Activities of the Society are:—

(a) The mutual interchange of ideas and experiences in Colour Photography by means of a circulating portfolio of specimens and MSS., which shall include questions and replies. This portfolio shall be circulated every three months, and shall not be retained by any member longer than five days.

(b) To obtain for members assistance by correspondence from more experienced workers, through the medium of the Hon. Secretary.

(c) To hold an Annual Exhibition in London open to members and non-members, at the time of the General Meeting.

(d) To form a permanent collection of Specimens, Apparatus, etc.

A most cordial invitation to join the Society is extended to all who are interested in the advancement of Colour Photography; membership is not confined to practical workers. Nomination forms may be obtained from the Hon. Secretary, Mr. Henry J. Comley, Surrey House, Stroud, Gloucestershire.

#### THE TRAILL-TAYLOR LECTURE.

ON Tuesday evening last, under the auspices of the Royal Photographic Society, at the New Gallery, the ninth Traill-Taylor memorial lecture, "Photography in the Work of the Greenwich Observatory," by E. Walter Maunder, was delivered. Sir H. Trueman Wood, in taking the chair, said that he did so only by reason of the unfortunate illness of the President of the Royal Photographic Society, General Waterhouse. Mr. Maunder said he had been a member of the staff of the Greenwich Observatory for a third of a century, and, being able to speak of certain features of the work done there from inside experience, he hoped to interest his audience—as he was certain that Mr. Traill-Taylor would have been interested—in the part which photography played in that work. Astronomy was the first of all the sciences to make use of photography since Daguerre attempted, at the request of Arago, to photograph the moon in 1839. The result was imperfect, but J. D. Draper, an American, obtained a series of Daguerreotypes of the moon in the March following, with exposures of twenty minutes, and in 1845 a Daguerreotype of the sun was obtained. Not long afterwards Greenwich Observatory pressed photography into its service, but Airy, the Astronomer Royal, elected to work by Fox Talbot's process of "photogenic drawing" on paper as being more suitable in many respects.

The purposes to which photography is now applied at the Observatory are, first, the recording of the changes in certain instruments; next, the pictorial representation of certain objects; and, thirdly, for the purpose of accurate measurement. Under the first head, Mr. Maunder showed by slides how photography was used in recording the movements of the magnetic needle, showing the changes in its intensity, and the changes in the direction of the earth's magnetism. The recording of the changes in meteorological instruments was another section of the same work. Slides made from early records printed on paper, prepared by a modification of Fox Talbot's paper, were shown.

Photography of the spots and faculae on the surface of the sun, of solar eclipses, etc., was not at first considered to be part of the Observatory's work, and it was not until the well known Kew heliograph was removed to Greenwich, in 1873, and placed under the lecturer's charge, that this work was carried out systematically. Referring to the sun spot photographs shown, Mr. Maunder said that the type of group which is most commonly observed begins its

life as a single small dot on the surface, and is usually joined by another spot close to it. The two spots grow rapidly in size, and separate as they grow, the movement being parallel to the sun's equator, and at the rate of about 8,000 miles a day. In the observation of nebulae and comets, photography enabled phenomena to be recorded which would otherwise be quite invisible.

The third head comprised work which had always been considered as coming within the original programme of the Observatory, and was the rectifying of the tables of the motions of the heavens and the positions of the fixed stars. Although the original purpose was the purely utilitarian one of assisting navigation, the progress of science had carried the work far beyond the limits of the warrant which defined the duties of the Observatory. Among the slides which illustrated this section of the work was one which showed how a planet, practically invisible, was differentiated from the fixed stars which surround it. Four exposures were given, the plate being shifted between each in such a way that the four images of each star formed a square, while the images of the planet, by reason of its movement, formed an irregular figure.

The chairman proposed a vote of thanks to the lecturer, and presented him with the Traill-Taylor Memorial Medal. Mr. Maunder responded briefly, and the proceedings terminated.

#### THE SALON AT THE ROYAL.

THE curious distortion of fact indulged in, quite innocently perhaps by Mr. A. C. R. Carter, in the critique of the Royal Photographic Society's Exhibition in "Photograms of the Year," deserves to be demonstrated by actual figures. Mr. Carter talks about the Royal being reinforced by the Salon, and instances twelve people represented this year at the Royal, who have "been seen at the Salon." We give the actual facts as to these twelve exhibitors for the past six years, from which it will be seen that it would be more accurate for Mr. Carter to congratulate the Salon on its reinforcements from the Royal:—

## Exhibitions.

#### ROTHERHAM PHOTOGRAPHIC SOCIETY.

THE Rotherham Exhibition was opened on Wednesday in last week at the Drill Hall, and during the four days it remained open attracted large numbers of visitors. The loan collection of photography by Herr R. Dührkoop placed at the society's disposal "The British Journal of Photography," was proved a special feature of the show. The awards in the competition classes were as follows:—

#### OPEN SECTION.

Photograph, any subject (previously medalled). Silver plaque. Fred Judge, Hastings.

Portraiture and Figure Studies.—Equal bronze plaques, Mrs. Dunlop, Motherwell, N.B.; F. A. Tinker, Sheffield; James Clark Ealing; Henry Holt, Rochdale.

Flowers, Fruit, Still Life.—First bronze plaque, D. W. Kyte, Glasgow. Second ditto, A. W. Walburn, West Hartlepool.

Landscape, Seascape, and River Scenery.—Equal bronze plaques

W. Cooper, Preston; Hy. Lindoe, Sunderland; Richard Harrison, Warrington; Charles E. Walmsley, Ambleside.  
 Architecture.—Bronze plaque, Alfred Roffey, Birmingham.  
 Lantern Slides.—First bronze plaque, A. G. Thistleton, Newton Heath. Second ditto, Graystone Bird, Bath.

## MEMBERS' SECTION.

Landscape, Seascape, River Scenery.—Bronze plaque, A. E. Dawson.  
 Architecture.—Bronze plaque, W. Firth.  
 Miscellaneous.—Bronze plaque, W. Firth.  
 Best board of exhibits.—Bronze plaque, H. L. Pontis.  
 President's prizes.—Bronze plaque, Miss Tillotson; bronze plaque, studies in three colour work, James Tasker.

## FORTHCOMING EXHIBITIONS.

September 14 to October 27: The Photographic Salon.—Sec., Reginald Craigie, 5a, Pall Mall East, London, S.W.

September 20 to October 27: Royal Photographic Society.—Sec., McIntosh, 66, Russell Square, Bloomsbury, London, W.C.

October 24 to November 14.—West of England Exhibition (Photographic Section). Entries close October 1. Sec., A. D. Breeze, 41, Lion Street, Plymouth.

October 31–November 1.—Watford Camera Club. Last day for entries, October 25. Secretary, Edwin H. Jackson, 5, Lower Derby Road, Watford.

November 7 to 8: Bedford Camera Club.—Sec., W. H. Hodge, 58, Baconfield Street, Bedford.

November 7–10: Motherwell Camera Club. Entries close October 5. Exhibits must be sent by November 2. Secretary, Jas. Dunlop, Rydebank, Motherwell, N.B.

November 7 to 10: Hackney Photographic Society.—Sec., Walter Hife, 70, Paragon Road, Hackney.

November 14 to 17: Rugby Photographic Society.—Sec., R. H. Myers, 13 Bridget Street, Rugby.

November 15 to 27: Burnley Camera Club. Entries close November 10.—Sec., Fred Whitaker, Mechanics' Institution, Burnley.

November 16 to 21: Southsea Amateur Photographic Society.—Hon. Sec., F. S. Hoyte, "Lismore," Stafford Road, Southsea.

November 20: Sefton Park Photographic Society.—Sec., A. W. Warr, 34, London Grove, Liverpool, S.

November 27 to 30: Hove Camera Club. Entries close November 1. Hon. Sec., G. W. King, 29, Wilbury Gardens, Hove.

December 5–8: North London Photographic Society.—Entries close November 26. Sec., Chas. Roberts, 33, Riversdale Road, Highbury, N.

December 6 to 8: South Manchester Photographic Society. Entries close November 21.—Secs., J. H. Haywood and M. W. Thompson, 45, Lapwing Lane, West Didsbury.

December 11 to 15: Southampton Camera Club.—Sec., S. G. Chamber, "Oakdene," Highfield, Southampton.

1907.

February 13–15.—Northern Tasmanian Camera Club. Last day for entries, December 31, 1906. Secretary, F. Styant-Browne, 112, Brisbane Street, Launceston, Tasmania.

February 23 to March 2: Birmingham Photographic Society.—Sec., Lewis Lloyd, Norwich Union Chambers, Birmingham.

February 11 to 14: Cripplegate Photographic Society.—Sec., J. B. Ashham, "Chagford," Old Church Road, Chingford.

February 12 to 23: Sheffield Photographic Society.—Sec., J. W. Wright, 62, Vale Road, Sheffield.

February 22 to March 4: Norwich and District Photographic Society.—Sec., J. T. Tanner, The Lodge, Norwich.

March 2–9: South London Photographic Society.—Sec., W. L. White, Bank House, Ladywell, London.

March 14 to 23: Leicester Photographic Society.—Sec., W. Murray, 60, Melton Road, Leicester.

April 29 to May 14: Photographic Society of Ireland.—Sec., R. Benson, 35, Molesworth Street, Dublin.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between October 8 and 13:—

PRINTING FRAMES.—No. 22,144. Improvements in photographic printing frames. Frank Ingram, 88, High Holborn, London, W.C.

PRINTS FOR COLOURING.—No. 22,196. Method of preparing or treating sensitised photographic surfaces which are afterwards to be coloured. Bernard James Cooper, 60, Queen Victoria Street, London, S.W.

COLOUR PHOTOGRAPHY.—No. 22,310. Improvements in cameras suitable for colour photography. John Snell Chenhall, 24, Southampton Buildings, London, E.C.

FOCUSsing.—No. 22,338. Improvements in focussing means for photographic apparatus. Walter Thorner, 111, Hatton Garden, London E.C.

CAMERAS.—No. 22,393. Improvements in photographic cameras. Frederick Hook and the Service Company, London, 23, Southampton Buildings, London, E.C.

PHOTOGRAPHIC ADVERTISEMENTS.—No. 22,394. Photographic apparatus, combined with a clock, barometer, or thermometer, for the purpose of photographic talking public advertisements. Umberto Majoli, 52, Chancery Lane, London.

CINEMATOGRAPHY.—No. 22,429. Arrangement for the centring of images in cinematographic projection apparatus. R. W. James, 1, Queen Victoria Street, London, for Compagnie Générale de Photographes, Cinématographes, et Appareils de Precision, France.

DAYLIGHT DEVELOPMENT.—No. 22,460. Apparatus for the daylight development of roll-film. Henry Masters and George Wishart, 96, Buchanan Street, Glasgow.

## COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

DEVELOPING P.O.P.—No. 13,032, 1905. This invention has for its object a new or improved process for printing and developing silver chloride paper whereby much greater speed of operation is obtained, the cost is very much lower than in the gold process, and the results are more brilliant, and show greater detail.

The invention consists mainly in using cyanides or sulphocyanides in the developer. One tablet of the developer is to contain 4 grains of pyrogallol acid with or without inactive material, and the other to contain one-thirtieth of a grain of bichromate of potash, one-fourth of a grain of sulphocyanide of potassium, and one grain of citric acid with or without inactive material, such as sugar of milk. These two pellets or tablets are dissolved in about five ounces of water.

Another formula giving excellent results can be obtained by a combination of the pyrogallol acid and metol in the one tablet,

and the bichromate of potash, sulphocyanide of potassium, and citric acid in the other tablet. The proportions are as follows:—

Pyrogallie acid .....	3½ grains.
Metol .....	½ grain.
Bichromate of potash .....	1-60th grain.
Sulphocyanide of potassium anhydrous .....	½ grain.
Citric acid .....	½ grain.

with or without inactive material, such as sugar of milk. In place of pyrogallie acid about the same weight of metol may be used. If metol be used it gives a blacker tone, and increases the speed of development. One and a half grains of metol and three grains of hydroquinone give a tone midway between pure metol and pure pyrogallie acid. There are other reducing agents, similar to these, which can be used in substitution of them, but not with such good effect. The bichromate of potash is used to increase the speed of development, and other alkaline bichromates can replace the bichromate of potash, but there is no advantage in using any of these over the potash salt.

In place of anhydrous sulphocyanide of potassium an alkaline iodide, sulphocyanide of sodium or even of ammonium could be used, but the ammonia salt discolours quicker. Alkaline cyanides can also be used to a certain extent, but none of these salts are equal in value to the anhydrous sulphocyanide of potassium. Although the hydrated salt will work equally well, the anhydrous salt can be made into tablets, and is not so deliquescent, whereas the hydrated salts are very deliquescent, and therefore it is difficult to keep them in pellets of exact weight and quantity.

The quantity of sulphocyanide too can be considerably varied; thus where a considerable amount extra is added, and the pinning is carried deeper in the first instance, a fine Bartolozzi red tone is obtained. The citric acid is specially pure and free from sulphuric acid and lime, and is deprived of its water of crystallisation. One grain of it equals 1.120 grains of ordinary citric acid crystals. It is used to make the developer work more evenly and to remove the bichromate stain. It can also be substituted in whole or in part by tartaric and other vegetable acids of a like nature; but citric acid is decidedly the best.

To obtain the address side of a postcard absolutely clean, addition is made to the developer of ¼ to ½ a grain of metabisulphite salt, of which potassium is the most suitable. This prevents the address side staining without interfering with the action of development.

The great difference between the process and any other is:—That whereas in all other known processes for developing silver chloride papers, as soon as the photograph is placed in a solution, the free silver which has not been reduced by action of light is washed out of the emulsion, is instantly attacked by the reducing agent, pyrogallie acid, metol, or whatever is used, and reduced to the black metallic state. This is deposited both on the dish and on the print, whereas with this process, by the addition of a cyanide salt to the developer, as soon as this free silver is washed out instead of being reduced to the metallic state by the reducing agent, it has a far greater affinity for the traces of the cyanide salt, and instantly flies to the traces of the cyanide salt and forms tiny yellowish white grains of cyanide of silver which will not stick to anything. Herbert John Mallabar, 59, Deane Road, Liverpool.

**TWO-COLOUR PHOTOGRAPHS.**—No. 22,725, 1905. The invention consists of the following process of printing from two-colour negatives taken through orange-yellow and blue screens respectively. From the orange-yellow negative a positive is made upon chloride of silver gelatine paper and fixed with ammonia whereby an orange-yellow monochromatic positive is produced.

A backing of celluloid is coated with a detachable emulsion such as used for gaslight paper, from the blue negative a positive silver print is produced upon this sensitised film, and is toned blue in a bath prepared somewhat according to the following directions: 50 parts of a solution of 1 gram of ferric-ammonio citrate in 100 grams of water are mixed with 10 parts of glacial acetic acid and 50 parts of a solution of 1 gram

potassium ferricyanide in 100 parts of water; the printing is placed for a short time in 2 per cent. hydrochloric acid and washed in water until the lights appear white.

The picture side of the still moist blue print is placed upon a celluloid backing, made to coincide with the yellow print produced under 2, having regard to the transparency of the backings, can be removed without loss of time and without difficulty. After dry celluloid backing can be easily stripped from the finished photograph, which moreover rests upon the paper by August Zimmerman, 3, Lloyd's Avenue, London, & Chemische Fabrik auf Actien (vorm. E. Schering).

**FOCUSSED FINDER.**—No. 25,948, 1905. The claim is for the construction of inclined planes or wedges as the mechanism of focussing finders may be made to perform their function when the lenses pertaining to such finders are of dissimilar length, as compared with their respective taking or lenses.

In the figure:—

A is a vertical rod sliding freely in sockets H H, which are attached to the camera-front or lens-board F.

A slight downward pressure is maintained on the vertical rod A by the spring E, so that a relatively uniform touch

A A by the spring E, so that a relatively uniform touch wheel C is maintained.

B is an inclined plane attached to the camera baseboard and a stop D at the top to prevent the wheel C from oversteering the end of the inclined plane.

I is a hollow tube, or collar, gripping on to the vertical rod A by means of the screw G, and is so designed that it is in contact between the face of the wedge J, and the focussing as well as between the face of the inclined plane B and the face of the wheel C can be readily maintained.

Q is the taking lens, while M is the focussing-finder lens.

N is a reflecting mirror at an angle of 45 degrees or thereabouts, and O the focussing screen of the finder, while DD is for the purpose of excluding extraneous light during the focussing.

S and T are the front and back portions respectively of the focussing finder, and these slide within one another telescopically.

The sliding movement to the body may, as an alternative, be accomplished by means of bellows, thus tending to greater portability. The front and back portions of the finder body are kept gently pressed towards each other by spring L, attached to the respective parts by lugs or

Harold William Hood, F.R.P.S., The Willows, Linthorpe, Middlesbrough.

**Patent No. 17,425. 1905.** The invention consists in the employment of a flexible cord across the centre of the dish, which passes through apertures in the sides of the plate at the centre; and in use, the plate or film will lie above the cord, and when resting on the bottom, this cord will lie within a transverse channel in the bottom of the dish.

In using the cord, the one or the other end, which has a knot or stop on it to prevent it running through the hole in the sides, is pulled by the finger and thumb, the effect of which is that the cord comes up against the bottom of the plate or film, and lifts it. William Laurence Parkinson, 3A, Imperial Chambers, 62, Dale Street, Liverpool.

**DIFFRACTION COLOUR PROCESS.—No. 6,825, 1906.** The invention consists in the improved form of the diffraction process, already described in the *BRITISH JOURNAL* for August 3, 1906. The first claims are:—

1. The process of making a diffraction colour photograph consisting in projecting on to a sensitive surface through three successive and different continuously-ruled diffraction gratings and three successive and different dispositions of clear spaces in a line screen or screens which may be arranged at an angle to the diffraction lines, rays from three successive images, each representing one of the primary colour sensations; substantially as hereinbefore described.

2. In the process of making a diffraction colour photograph a line screen having opaque spaces twice as wide as its clear spaces, rays from three successive images, each representing one of the primary colour sensations, and shifting the line screen between successive exposures to the extent of the width of each of its clear spaces. Herbert Eugene Ives, Woodcliffe-on-Hudson, Weehawken, County of Hudson, State of New Jersey.

**PHOTOGRAPHY.—No. 19,272, 1905.** The invention relates to Patent No. 29,057, 1904, and relates to a device for displaying a double series of pictures by aid of a single light, and with or without the use of revolving or other shutter mechanism. A single source of light is provided, and at a suitable distance in front of the light two mirrors are placed one beside the other at right angles to the light and at right angles or some other suitable angle to each other. Robert Thorn Haines, 26, Osna-  
burgh Street, London, W.

The following complete specifications are open to public inspection and acceptance under the Patents Act, 1901.

**Patent No. 22,338, 1906.** Focussing methods and means for photographic apparatus. Thorner.

**PHOTOGRAPHY (U.S. Pat.).—No. 287,188. July 31, 1906.** A suitable paper is coated with an emulsion of an animal glue (e.g., fish-glue), containing a red dye stuff, for which alizarine is recommended. It is slightly hardened by means of alum solution, and sensitised by treatment with an alkali bichromate solution. An image is printed from this paper from a negative taken through a suitable screen, and this image is coated with transparent sensitive coating, which receives a blue image of the same object.—W. C. South, Berwyn, Pa.

**Old Lens.—**A correspondent writes:—"If your inquirer will get the lens again I think he will find the name on it is Burton, London. Burton was a very good working optician who kept all shop at the east end of Church Street, Minorities, London, E., near the little church of Holy Trinity (where, by the by, I was organist at the early age of 15). He made some very good Petzval lenses of the Petzval type, but I never knew of his making binoculars. He was particularly good at binocular opera glasses, and made for me one of the finest pairs I ever used (and which I unfortunately, at the Handel Festival of 1865). He has been dead many years."

**Late P. M. Laws.—**Mr. Peter M. Laws has just died at Newbury in his seventy-fifth year. He took up photography when it was in its infancy, and was a pioneer in the use of artificial light.

## New Books.

"Photograms of the Year." 1906. London: Dawlarn and Ward. 2s. and 3s.

This hardy annual comes in a new guise this year. Its cover is perhaps a trifle old-fashioned in design, but, on the whole, it is a handsome book. The publishers disarm criticism by explaining their aim to reconcile quick production with good printing. Certainly they have not entirely achieved the latter for the pictures, in spite of the "art paper," the necessity for which all publishers nowadays seem to make a virtue of. The text, however, is a typographic triumph. The matter, too, is both entertaining and instructive. For the most part it is made up of reports as to pictorial progress in America, Canada (a nice distinction to the ordinary Britisher), Australia, Spain, France, and of course, England; but of Germany and Austria we are told nothing.

Roland Rood's article on America is fresh and level-headed. It says that the "winning of the recognition of the painters" is the chief aim there. Mr. Rood commends their Salon for its sanity, its freedom from "purism," eccentricity, and decadence. This fact he attributes to the work "having passed before a jury of artists, and not before a body of youthful art-students and amateurs." In the special exhibits that followed the show the French elicited interest and amusement; the German were much more appreciated; but of the English (D. O. Hill, Craig Annan, and F. H. Evans) only Hill's was well received. Craig Annan's was too various in style to make an impression, and Evans's lacked the exaggeration that appeals to the emotions—"the audience wanted to be amused, not instructed." Steichen is said to have the secret for the master-stroke. His "Rembrandts" and their "empty shadows" "touch the right spot," but as soon as he puts something into these shadows "Rembrandt goes, and so does the charm," "to be made to feel, that's fun, but not to think." We should have thought all that a pretty bad look out for America.

H. Mortimer Lamb sounds a doleful note. The Toronto Camera Club is congratulated upon its "having cut out the high-sounding title of 'Salon'"; but one of its highest achievements is A. S. Goss's 'Child and Half-Nurse,' now at Pall Mall. So much for Canada! We like the pessimism of Mr. Lamb's article; it argues good taste.

On the other hand, A. Hill Griffiths writes with exciting optimism about Australia. "We have had glimpses of the various fads and fancies which have been introduced under the heading of 'Pictorial Photography,' but fortunately no one has been persuaded to adopt them." The British Affiliation comes in for rebuke, on the scores of both manner and matter. Speaking of the pictures sent out from England, Mr. Griffiths says: "O deliver us from any desire to express ourselves in such gloomy sentiments." He prognosticates a great artistic future for the colony, to be arrived at by doing its "own lonely road." "Plainly speaking," he says, "there is practically nothing to be learnt from our gaze into British pictures. . . . I think we can do better." A praiseworthy, typical, colonial sentiment.

M. Mendez Leon informs us that Spain has her "Velasquez of photography" in the shape of a hitherto obscure professional. There is no "crowd of amateurs" in Spain. As to him who takes up snapshotting with "small apparatus," which weighs very little, "his results are not, as a rule, exhibited." What a happy place is Spain! There appear to be, however, countless exhibitions in which prizes are awarded, the prize-winner having to surrender his rights in everything he exhibits, which all become the property of the promoters of the show. In spite of this drawback, however, "there appears to exist a rooted preference for actual prizes instead of honourable mention." So after all the plan seems to be mutually satisfactory. M. Leon concludes in these words: "Work has been done in Spain but not on the surface (we have heard, indeed, that dark rooms are sometimes subterranean in that happy land), and will not be produced until the worker is assured of securing an honoured position." America had then better "watch out."

A brief but excellent article from M. Robert Demachy sums up the state of things in France, where printing methods that admit of

control have ousted "straight" photography. He says all those who do not know how and where to improve and correct a straight print are "dropping, one by one, out of the race, and they are aware of it."

As usual, Mr. Carter supplies the appreciation of the Salon and Royal shows; but struggles this time with the Herculean task of making out a bright case for the former and a sorry one for the latter. "I must make it clear," he says, "that the present reduced Salon is more preferable to me than any I remember." He implies, further, that the excellence of the Royal show is due, in some mysterious way, to the Salon. These opinions have the merit of being unique.

We can heartily recommend the book as being a perfect compendium of all the best photographic work done during the past year, whether exhibited or not. It contains nearly one hundred and sixty reproductions of work done at home and abroad, and is by no means a mere réchauffé of the London exhibitions. Readers will find a very large proportion of pictures which are new to them, and which they will probably see nowhere else.

"Stereoskopbilder vom Sternhimmel." Series 1, Von Prof. Max Wolf, Heidelberg. (Leipzig: Johann A. Barth, 1906.)

Some months ago Herr Prof. Max Wolf, of the Königsstuhl Observatory at Heidelberg, made the interesting announcement that he had been able to construct true stereoscopic charts of the sky, and very soon following the preliminary announcement a picture was issued showing a variable star on the starry sphere. Viewing this with an ordinary stereoscope, it was marvellous how any slight changes in the positions of the various stars were rendered manifest, and it was found not only possible to demonstrate the actual proper motion of a celestial object in space, but to measure its amount with extreme accuracy. Now this is an accomplished fact it appears as simple as it is beautiful, but it has involved the greatest refinement of patience and accurate manipulation on Prof. Wolf's part to secure its accomplishment. The distances of most of the celestial objects are so nearly infinite that the two stereoscopic component pictures cannot, of course, be obtained by any change of position of the camera, so what Prof. Wolf did was to take one picture and then, after the lapse of several years, a second; the instrument must of necessity be at the same adjustment in the two cases so as to maintain the scale constant.

The small collection of stereograms under review—twelve in number—is in itself excellent testimony to the thoroughness of the work. The plates show a variable star, R. Coronæ—one view taken 1903 (May 28), the other 1905 (May 7); the planet Saturn, with its satellites; the asteroid Svea (329), for which the exposures were fourteen minutes apart on the same evening, each exposure being about two hours; a meteor or shooting star; comet Perrine (1902); proper motion of a star in Orion; the Nebula of Andromeda, taken at four years' interval; the Orion Nebula, with two years' interval between the component photographs; two regions of the moon, with the lunar Apennines and the crater Albategnius.

To one accustomed only to the usual single pictures of these celestial objects it is a revelation to see the extra detail brought out by this new method of observation. The photograph of the Andromeda Nebula, projected on a background of brilliant point-like stars, is a most beautiful object. As these photographs become more widely known they promise to be of great value in cosmical determinations, and they should also prove useful to teachers of astronomy in giving concrete proof of various matters difficult of direct explanation.

A LANTERN list from the Kodak Company, Clerkenwell Road, London, E.C., is offered free to applicants, and will be found to contain descriptions of a great variety of lantern and enlarging apparatus.

MANCHESTER Amateur Photographic Society.—The 21st annual exhibition will be held at the Manchester Athenæum, from November 5 to 10. A programme of lectures has been arranged for the period of the exhibition. Particulars are obtainable from the secretary, Mr. F. W. Parrott, Elm House, Elm Road, Altrincham.

## New Apparatus, &c.

Century Cameras. Sold by Kodak, Ltd., 57 to 61, Clerkenwell Road, London, E.C.

A series of about a dozen patterns of cameras has been introduced to the British public by the Kodak Company, on the assumption that, despite the immense variety of apparatus already obtainable, there is yet room for another series of instruments of sufficient distinctive features. These latter in the Century cameras are of some considerable practical importance, and of a kind also which, should judge, will be appreciated by the dealer who desires to maintain a full stock.

the best possible case for the camera to purchasers at the counter. The Century cameras have

- Revolving reversing back,
- Swing bed,
- Focussing screen in automatic register,

and are fitted with finders which can be easily taken to pieces, cleaned. Such are the salient features of the new introduction. Perhaps we can best describe them in reference to two particular instruments, selecting for this purpose the "Petite Century, No. 1" and the "Century Grand Senior."

The former is shown in the drawing, from which it will be seen

that the cameras are of the hand-stand pattern, the particular of the series being with double extension, fitted with automatic clamp for the lens front, by which the focus is fixed in an instant and the front released with equal ease and rapidity. The finders has rising and cross movements, in both cases actuated by rack and pinion. It carries automatic shutter, reversible finder, and

in appearance as good-looking an instrument, as we consider it to be well equipped for practical work. The prices are: £3 18s. in quarter-plate, £4 15s. in 5 x 4, in each case including one double dark slide.

In the "Grand Senior" model, all the most varied requirements of the photographer have been studied. The camera is of triple extension (16½ inches—5 x 4 size), and is also fitted for the very shortest wide angle work by the provision of an extra detachable bed to support the front, the baseboard falling down completely out of the way, as shown in the illustration. The camera has swing front of the usual pattern, but for this wide angle position an additional swing is provided. All the other usual movements, such as rise and cross movement of front, are available, and, for the price of £11 in the 5 x 4 size the camera is fitted with superior R.R. "Centar" lens. The price in 7 x 5 is £13, and in 8½ x 6½, £16 15s.

## New Materials.

The Wellington S. C. P. Lantern Slide. Made by Wellington and Ward, Elstree, Herts.

Appropriately at the commencement of the lantern season, Messrs. Wellington and Ward introduce their gaslight emulsion as a lantern slide. Under the title S.C.P. they are issued at the standard prices for lantern slide plates—viz., 1s. per dozen, ¾ x ¾. These are packed in pairs, face to face, being held together by unsevered film of emulsion. Testing a sample on some fairly quick-printing negatives, we found an inch of magnesium ribbon burnt at about 4ft. distant approximately right for correct exposure. With this degree of exposure and using the maker's normal developer of:—

Water .....	20 ozs.
Metal .....	20 grs.
Sodium sulphite .....	200 grs.
Sodium carbonate .....	800 grs.
Hydroquinone .....	20 grs.
Potass bromide .....	20 grs.

we obtained fine black tones. The plates develop very quickly, in less than a minute, and the image is of very fine grain and great transparency.

By giving exposures up to twice or three times the normal and adding 1 to 2 drachms of the following restraining solution, tones from warm brown to red are obtained:

Ammonium carbonate restraining solution .....	1 oz.
Ammonium bromide .....	1 oz.
Water .....	10 ozs.

Development, of course, is slower in this restrained bath, but the range of colours obtainable pleased us extremely, and no one can be pardoned for inflicting a series of monotonous black slides on an audience when there is the Wellington S.C.P. plate at his disposal. We congratulate Messrs. Wellington and Ward on their new introduction.

"Zigas" Gaslight Paper. Made by Thos. Illingworth and Co., Ltd., Willesden Junction, London, N.W.

Messrs. Illingworth have introduced a companion to their "Zigo" self-toning paper in the person of "Zigas," which is a gaslight paper, made in four qualities: ordinary matt and glossy, and portrait matt and glossy, the two latter brands yielding softer prints, but resembling the "ordinary" paper in surface. As a result of preparing prints in all four grades, we have seen that "Zigas" is a very clean working gaslight paper. Its disposition to fog is noticeably small, and we were satisfied by our trials that the new introduction may take its place among papers of acknowledged quality without fearing comparisons.

To stimulate interest in "Zigas" the makers have arranged a competition for prints made from it, in which £50 in prizes will be distributed.

Falla-Gray Gaslight Papers. Made by the Falla-Gray Photo-Paper Company, Park Road, Tunbridge Wells.

Our paragraph of a week or two ago, alluding to the exhibit of the Falla-Gray Company's exhibit at the New Gallery, has brought us a sample of the paper from the makers, who draw our attention

to its two special qualities—rapidity of (1) development, and (2) fixation. In the course of making a dozen or two of prints upon the paper we were at once impressed with the almost instantaneous manner in which the image attains full vigour. In fact, we found that it was best to adjust exposure so that the print developed thus quickly; the slightest forcing of development led to general fog. In regard to the second claim, the makers in their circular state that fixation is complete in a (fresh) bath of hypo, 4 ozs. per pint, in one minute. This point we confess did not interest us much, since we cannot imagine any working condition in which this speed of fixation would be of any great value. Theoretically, the fact may be of interest, and we hope to make some further prints, fix them exactly for one minute, and note the results of exposure to light and air. The makers state that in case of a longer fixation than one minute a proportionate time of washing must be allowed. We suppose they mean longer, but we cannot quite enter into their reasons for the advice. However, worked in the ordinary way Falla-Gray is a very good gaslight paper, and we can recommend it. For tones in imitation of P.O.P. the makers give the following process:—

### Solution 1.

Mercury perchloride .....	2 drms.
Ammonium bromide .....	1 drm.
Common salt .....	4 drms.
Water .....	10 ozs.

### Solution 2.

Soda sulphite, pure .....	½ oz.
Water .....	10 ozs.

The prints, after being well washed, are immersed in the mercury bath until bleached, then thoroughly washed and placed in the sulphite bath until the desired colour is obtained, care being taken not to tone too far as they dry much colder. They are then washed for five minutes, and rinsed and finished in the usual way.

### CHRISTMAS STATIONERY AND ACCESSORIES.

Chic Christmas Mounts.—These mounts are the special issue of Messrs Kodak, Ltd., who for the last year or two have offered attractive series of mounts at Christmas under the above title. The specimens before us of the present year's styles include some of the most truly artistic productions we have seen. They are all of a matt or rough surface, produced in varied shades of greys, greens, and other colours. Some, of a marbled surface, are very effective, and we can quite recommend application for the four-page circular in which the mounts are priced and illustrated.

Christmas Motto Mounts.—Messrs. Houghtons, Ltd., remind us of their series of Christmas mounts by sending us the catalogue and circular of trade terms for the various series published by them. The list is fully illustrated in half-tone, a help to the purchaser who cannot personally inspect the cards. A book of specimens is issued for half-a-crown, which sum is refunded on receipt of an order of £2 10s. and upwards.

Seltona Christmas Postcards.—The Leto Photo-Materials Co., Ltd., Rangoon Street, London, E.C., have ready their well-known Seltona emulsion on postcards bearing suitable mottoes for the Christmas season. This special issue of the self-toning cards applies to both the matt and glossy varieties. A packet of twelve cards and two masks is sold for one shilling.

Christmas Motto Negatives.—Mr. H. W. Green sends us samples of new Christmas motto negatives, which are sold by him in assorted packets for 7d. post free. The negative allows a motto to be added to a photograph without an extra operation in the printing.

A further selection of Christmas mounts reaches us from Jonathan Fallowfield, of 146, Charing Cross Road, London, W., accompanying a forty page illustrated list. This latter is the most extensive piece of literature dealing with this type of goods, and contains particulars of a special offer to dealers and professionals in the shape of specimen packets of mounts made at 5s. and 7s. 6d., made up in sizes specially to suit customers' requirements. Of the cards themselves we can only select one or two which we specially like, while referring the reader to the illustrations in the list: No. 664, rough art paper, like Whatman drawing paper, tied with silk bow; No. 676, white ivory card, embossed in gold with motto;

No. 1,051, single card with strut back, oval opening and surrounded by ribbon design; No. 1,009, rough cream art paper with deckle edge, and embossed design with motto in gold, green and red, a very handsome card. We are glad to see the firm offering their accustomed variety.

**ENTENTE CORDIALE POSTCARDS.**—Mr. E. Alexander, the agent for the "Aristophot" Co., sends us a series of postcards just issued by him apropos of the visit of the Lord Mayor to Paris. The cards are apparently hand-coloured glossy bromides and extremely effective. Prices, etc., from 104, Southampton Row, London, W.C.

**MOUNTING PAPERS.**—We have received samples of art mount papers from Messrs. Barton, 114, Golden Hillock Road, Birmingham, which should interest all those who read Mr. Gordon Chase's letter in our last issue. The papers include a number of canvas-like surface, others resembling linen, and in all respects are of excellent appearance and colour.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Oct.	Name of Society.	Subject.
26.....	St. George Co-op. Soc. Cam. Cl.	"What Can be Done with a Hand Camera."
26.....	Photo. Society of Ireland .....	"The Pictorial Possibilities of P.O.P." Alfred Waring. "Dry Mounting." Demonstrated. H. C. Draper, F.C.S.
27.....	Aberdeen Photo. Art Club.....	Ourling to Bieldside.
29.....	Forest Gate Photo. Society...	"Hford Lantern Plates," A. Brooker.
21.....	Oxford Camera Club.....	An Exhibition of Novelties in Apparatus.
29.....	South London Photo. Soc'ety...	"A Lantern Slide-Making Competition." Gideon Clark
29.....	Southampton Camera Club .....	R.P.S. Affiliated Societies Prize Slides
29.....	Preston Camera Club .....	"Outdoor Figure Work." T. H. Greenall.
29.....	Caterham Valley Photo. Soc.	"Latest Kodak Productions."
30.....	Glasgow Southern Photo. Assn.	Members' Lantern Slide Competition.
30.....	Darlington Camera Club .....	"Lettering and Titling." R. W. Chapman.
30.....	Manchester Amat. Photo. Soc.	"Velox Printing." J. J. Phelps.
30.....	Hackney Photographic Society .....	"Combination Printing." J. Linley.
30.....	Glasgow Southern Photo. Assn.	Last Date for Sending in Prints for Federation Portfolio.
31.....	Croydon Camera Club.....	"The Carbon Process." Mr. Braham.
31.....	Bideford Camera Club .....	"The Photographic Lens." C. P. Goerz.
31.....	Woodford Photo. Society .....	"Velox." Demonstrated. A. W. Green.
Nov.	Chelsea and District Photo. Soc.	"Pictures with the Goerz Lens."
1.....	Rugby Photographic Society .....	"The Theory and Practice of Self-Toning Papers." Messrs. J. J. Griffin & Sons.
1.....	Hull Photographic Society .....	"The Cathedral of Winchester." S. G. Kimber.
1.....	Liverpool Amateur Ph. Assn....	"The Photography of Flowers." Demonstrated. Dr. A. T. Lakin.
1.....	North London Photo. Society....	"Old Inns and their Story." J. H. K. Todd.
1.....	London and Prov. Photo. Assn.	"The Rendering of Colour and Colour Contrasts." C. E. Kennerth Mees.
1.....	Blenheim Club .....	"Forest Life." T. Martin Duncan.
1.....	Richmond Camera Club .....	Members' Slides.
1.....	Chelsea Photographic Society....	"Pictures with the Goerz Lens."
1.....	Small Heath Photo. Society .....	"Telephotography." C. P. Goerz.

**HULL PHOTOGRAPHIC SOCIETY.**—In dealing with cristoid films and their possibilities last week, Mr. W. Whitlam sent round negatives (with prints from them), many of which were quarter plate exposures stretched during manipulation to 5 x 4 and up to half plate, yielding that soft and desirable falling off of pinwire sharpness so objectionable to pictorial workers. In demonstrating upon an exposed spool it was first placed in the hardening bath of 2oz. formalin to 1 pint water. The film became so limp as to have the appearance of a dish-cloth, and it seemed impossible to harm it, and there appeared to be no chance of scratching or finger-marking it. This done it was thoroughly washed and placed fold over fold in the developer, which was completed quickly, to the surprise of many. The six exposures dealt with had received upon the same subject from a fraction of a second up to four seconds, and they had been given as much as seven times the normal exposure, and excellent results secured as against hopeless failure

with glass plates. A half plate film was successfully enlarged to whole-plate size during the evening by the aid of hydrochloric acid and water.

**CROYDON CAMERA CLUB.**—Mr. H. P. C. Harpur, on the 17th inst. gave a demonstration on the making of lantern slides, and a most complete exposition of the subject could hardly have been wished for. At the onset an inspiring touch was afforded by the strain of a powerful brass band outside, which competed severely at times with the lecturer's voice. Mr. Harpur, in opening incidentally deplored the existence of the musicians, and also the fact that poorer and poorer slides were shown each year. This he attributed to the reluctance of members exhibiting their slides more than once, and a lot of trouble was therefore incurred for very little return. Prints, on the other hand, could be framed and be always in evidence. For the production of first-class slides, cleanliness in working, purity of chemicals, and standardisation of methods were in his opinion, essential. Even the fixing bath should be filtered and personally he invariably used fresh hypo solution for each plate. He preferred warm tones by restrained development, adopting the following formula:—A pyro tabloid (grain 2), was dissolved in drachms of water, 40 drops each of 10 per cent. solutions of carbonate of ammonia and bromide of ammonium, were added, and finally 21 drops of a 1 in 10 solution of ammonia .880. The bottle containing these solutions were numbered from 1 to 3, by sticking on punched-out black discs, one disc for No. 1, and so on. These showed clearly in the dark-room, and prevented mistakes. He developed for a fixed time, the correct exposure being ascertained by slip tests in the usual way. The most suitable negative, in his opinion, was one which would enlarge well by artificial light. One number of capital slides by Mr. Harpur were then shown. One entitled "Reflections" (about seven-eighths of its area consisting of somewhat frozen reflections, and the remaining one-eighth terra firma), in the opinion of the majority looked best the wrong way up. The lecturer then passed on to a consideration of slides by reduction and combination printing, which operations were much facilitated by most ingenious appliances of his own design. During the evening the President, Mr. W. H. Smith, read the letter appearing in the current issue of THE BRITISH JOURNAL OF PHOTOGRAPHY, from Mr. J. B. B. Wellington, appealing for assistance on behalf of Mr. J. T. Sandell. He cordially endorsed its contents, and hoped all photographic societies would try and help a little towards the alleviation of one who was so sorely stricken. Messrs. G. W. Watson, L. Kough, and E. A. Salt also spoke in terms of sympathy for the sufferer and his family, and a sum of £5 5s. was subsequently collected from those present.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.** Meeting October 18, Mr. J. S. Teape in the chair. Mr. Freshwater read paper entitled "Photographic Notes," in the course of which he alluded to the many things of interest which are daily passed by without notice by the majority of people. He referred particularly to the phenomena to be observed in any English meadow or on sea-beach. Lantern slides were projected showing the home of the frog and the frog from the spawn to the full-grown old stager. Sections of the agate, the diamond, etc., and yet again of various parts of the coast, showing its formation, of snails, caterpillars, spiders, frost on glass, each of which were accompanied with full description. A hearty vote of thanks to Mr. Freshwater was proposed and carried.

**ROYAL Photographic Society.**—On Tuesday week, November 6, the session of the Royal Photographic Society will be opened by a reception by the President and Council at 8 p.m. This function (which it is intended should be an evening dress one) will mark the re-opening of the society premises after the alterations to the lecture room. A short address will be delivered at 8.30. A house exhibition of photographs, by Mr. H. W. Bennett, will also be opened, and, in addition, there will be on view:—Examples of work done with the Pulligny anachromatic lens, by R. Demachy, C. Puyo, G. Besson and A. Hachette; portraiture by the Schott-Genossen mercury-vapour lamp, by A. W. Isenthal; selected objects under microscope, by R. and J. Beck, Ltd.; printing by the mercury-vapour lamp, by O. Sichel and Co., Ltd.

## Commercial & Legal Intelligence.

**BERNARD COOPER, LTD.** (Photographers, London).—A third debenture for £100, dated September 29, 1906, charged on the company's undertaking and property, present and future, including uncalled capital, has been registered. Holder: Mrs. M. M. Hadfield, 28, Victoria Mansions, Willesden Green.

**THE Barnet Seaside Competition.**—Messrs. Elliott and Sons, limited, inform us that the last day for receiving entries for the above competition is Wednesday next, October 31.

A MEETING was held in Manchester, on October 17, of the creditors of Frederick Arthur Brown, a photographer, of The Cliff, Higher Broughton. The total liabilities amounted to £157, and the deficiency £78. The matter was left in the hands of the Official Receiver.

**HENR Husband's Portrait.**—One of Mr. Plowden's numerous visitors last week was a woman who complained that a photographer, who had undertaken to make a copy of a photograph of her husband for a sovereign, had spoiled the picture, and now wanted to charge her an extra 3s. 6d. to make another copy. Mr. Plowden: Well, of course. He has gone to extra trouble, extra time, and extra skill to do justice to your husband. Applicant: What! 23s. for one picture? Mr. Plowden: He is worth more than that, isn't he? Applicant: No, it isn't worth that. Mr. Plowden: Well, you know him better than I do. The applicant then withdrew, and as she left the Court she muttered, "I'll lose the 16s. I've already paid before I'll pay any more."

**PICTURE Postcard Dispute.**—At the Croydon County Court, last week, the Photo Printing and Publishing Co., of London Road, Croydon, claimed from J. Tufnell, stationer and newsagent, of Church Parade, Newbury, the sum of £23 10s., the price of certain picture postcards. Defendant counterclaimed £25 as damages, alleging that for a certain quantity of postcards he was given the sole right of sale, whereas plaintiffs let another tradesman have a supply subsequently. The case occupied a considerable time. Plaintiffs admitted giving defendant the sole right to the sale of certain albums of postcards supplied to him by them, but produced the signed contract for the supply of 2,500 coloured postcards, each of 12 subjects, which contained no clause giving him the exclusive right of sale. That was the agreement on which defendant alleged that plaintiffs were committing a breach. As to plaintiff's claim, defendant alleged that a second contract was substituted for the first. The Judge, in giving his decision, said as regards the plaintiff's claim a perfect binding contract had been shown, whilst the story of the case did not entitle defendant to maintain his counterclaim for the counterclaim. He gave judgment for plaintiffs on the claim and counterclaim.

**PHOTOGRAPHER and Circus Troupe.**—An exceptional charge of false pretences was brought at Blackpool yesterday morning by W. Koeppe, a German travelling with Novello's troupe of elephants, against Fred J. Cawsey, principal partner in the firm of Cawsey and Burtonwood, photographers, of Skipton Street, Morecambe. Mr. Callis, who represented the prosecutor, said that although the summons was issued for false pretences he thought they would find that the technical offence with which he charged him was stealing money by a trick. Prosecutor wrote to the firm for three large photographs and twelve post-cards, and in reply received a letter stating: "I may say that owing to having such a lot of money lying me from the profession we have to make a rule of cash at time of ordering," and quoting three large photographs at 1s. 6d. each—(4s. 6d.), twelve post-cards (3s.)—7s. 6d. Having got the money a letter was received as follows:—"We are in receipt of postal order value 7s. 6d. in part payment of photographs sent to the King's Theatre, Gateshead-on-Tyne, on June 16, 1906 (three months before) as per arrangement when you were in Morecambe." Then followed "six photographs at 1s. 6d.—9s., paid on account, September 20, 7s. 6d., balance 1s. 6d." The meaning of all that, said Mr. Callis, was that the money sent was put to the credit of a bill of 9s., which prosecutor had never heard of. Mr. Butcher, who appeared for the defendant, said that defendant's case was that shortly after Whit-week, whilst Mr. Novello's troupe was appearing at Morecambe Winter Gardens, he had them photographed.

Koeppe gave an order for six cabinets to be forwarded, and this was done. He still owed them 1s. 6d. At the conclusion of the evidence Mr. Callis said that if defendant would return the prosecutor his 7s. 6d. and pay the costs of the prosecution he would not ask anything further. Mr. Butcher did not agree to this course, and the Bench fined the defendant 5s. and costs, and ordered the return of the 7s. 6d. paid by Koeppe.

### NEW COMPANIES

**MATTOS, LTD.**—Capital £24,000, in £1 shares (2,000 preferred ordinary and 2,000 deferred ordinary). Objects: To acquire the process of P. Leuthardt-Thornton for the preparation of paper for photographic purposes, and to acquire the business of a manufacturer of photographic paper carried on by the said vendor. The first directors are E. W. Hunter (chairman), H. N. Hunter, and P. Leuthardt-Thornton. Qualification, £250. Remuneration as fixed by the company. Registered office, 36, Arundel Square, London, N.

## Correspondence.

*\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*\*\* We do not undertake responsibility for the opinions expressed by our correspondents.*

### THE SENSITOMETRY OF PLATES.

To the Editors.

Gentlemen,—In reply to Mr. Gascoigne's letter in your issue of October 11, it appears to me that there is some slight confusion of terms. I expressly stated that our screen was only correct to 3,700, and that it would be better, if possible, to go below this. But the large amount of ultra-violet in daylight, which is active, is mainly between 3,700 and 4,000, and this amount is corrected by the screen. Mr. Gascoigne's statement that the ultra-violet, even beyond 3,700, is non-existent in acetylene, is incorrect. The ultra-violet is simply weak compared with the red, and the correction can be made to any point fixed, by absorbing the red. We fixed that point at 3,700. The ultra-violet of daylight is absorbed by most lenses at 3,500 (Newton and Bull, P.J., July, 1906), so that the uncorrected portion remaining is the excess of ultra-violet in daylight over screened acetylene between 3,700 and 3,500.

The absorption of "Filter Yellow K." as compared with tartrazine is chiefly notable between 3,700 and 4,100, which weak tartrazine screens pass, this, while in the ultra-violet, is also in the portion corrected by the screen. Moreover, reference to Newton and Bull's paper will show that the strongest band in the enclosed arc is between 3,700 and 3,900.

Personally, I think that the main value of this screen is in testing strongly colour-sensitive plates for speed. Mr. Ferguson, who is at present away from books and references, has asked me to reply to Mr. Gascoigne in reference to his factor 0.4186 in his letter of July 27. This is the  $\frac{1}{2.41}$  of the line above converted into a decimal, but apparently converted wrongly, for it should be 0.4651, probably an arithmetical error. The rest of the calculation should be altered to correspond. Permit me to agree with Mr. Piper as to the undesirability of restricting research funds from expenditure on permanent apparatus. The cost of permanent apparatus frequently causes the publication of most unsatisfactory and inaccurate results, simply because the means of making those results accurate were not at hand.—Yours faithfully,  
C. E. KENNETH MEES.

Croydon.

### THE STABILITY OF PYRO AND SODA DEVELOPING SOLUTIONS.

[NOTE.—Through a clerical error last week the name of Mr. S. E. Sheppard, B.Sc., was omitted at the foot of the letter by him on the chemistry of sulphite in developers.]

To the Editors.

Gentlemen,—In your comments on my last letter on this subject

you asked for the actual composition of a working developer, and the time taken for attaining full density, in my ordinary work.

For a subject of normal contrast the developer would be:—

Pyro .....	1½ grains.
Potassium meta-bisulphite .....	1 grain.
Potassium bromide .....	1 grain.
Sodium carbonate .....	12 grains.
Sodium sulphite .....	12 grains.
Water .....	1 ounce.

and the time necessary for attaining sufficient density and contrast to give a strong and vigorous platinotype print would be from six to seven minutes, at a temperature of 65 degrees Fahr.—I am, Sirs, yours truly,

HENRY W. BENNETT.

To the Editors.

Gentlemen,—I have been very interested in the articles, and your notes and advice re pyro-soda developer, and having had difficulty with deterioration when using a certain standard formula, I have just adopted your recommended new formula, which I intend to give a good trial and closely watch. I should value your advice as to an economical developer expressly for use, with very short exposures. In the formula I use pyro-metol. Sodium carbonate and sodium sulphite are in one solution, which I wish to avoid. If possible I would rather modify your formula above mentioned, to use in cases of very quick exposures.—I am, dear Sirs, yours faithfully,

1, London Road, Grantham. A. M. EMERY.

October 20, 1906.

[We have not tried our formula for very brief exposures, but see no reason why it should not answer. We should be disposed to use it diluted and give plenty of time. As it is clear and not inclined to give great density, it should be well suited to prolonged development. The pyro metol formula you mention can easily be altered by transferring the sulphite from solution B to A. Dissolve the sulphite first, then the metabisulphite in about 20 ounces of water. Add the pyro to this solution, and dissolve the metol separately in 15 ounces of plain water; then mix the two solutions. We shall be glad to hear if our pyro-soda developer works well with brief exposures.]

#### THE P.P.A. EXHIBITION.

To the Editors.

Gentlemen,—The criticism (?) which appears in the "Times" on the exhibition by the Professional Photographers' Association, now open in your offices, is of such a nature that some little comment is called for. The writer, whoever he may be, states that "in most pursuits amateurs are unable to hold their own against professionals. The one class usually brings a certain amount of perfunctory zeal to bear on the subject, while the other, under the pressing necessity of gaining a livelihood, misses no opportunity of improvement. It would seem, however, that photography is an exception; for here it is the amateur who undertakes experiment and works for advancement, while the professional lingers far in the rear. . . . They continue to produce portraits of people who are obviously sitting for their portraits. . . . It is stated that they are 'fettered by commercial limitations'; but this is a plea that should scarcely be used by conscientious craftsmen who wish to give the public of their best. Moreover, the public would soon learn to distinguish between an artistic and 'commercial' photograph if the professionals combine to raise the standard of production."

Let me, at the outset, state that I am not an exhibitor, and therefore am not suffering from any personal feeling in the matter; I am merely craving for enlightenment. Being under the pressing necessity of gaining a livelihood, although one philosopher at least has told us that this is unnecessary, what am I to do whilst the public is being educated to distinguish between the artistic and "commercial" photograph?

Surely, when I produce portraits of obviously sitting people of such a quality and quantity that I can live comfortably and educate respectably a family of five, so that they shall in turn earn a livelihood, I have fulfilled my duty as a citizen of the State. Am I to follow the lead of some of the amateur workers, who exhibit at the R.P.S. and the Salon and produce things which require a title to explain what they are? Will the public buy these things as "likenesses"? If not, am I to sit on my hunkers and wait till they learn to appreciate them?

My experience, though "fettered by commercial limitations," for

the last twenty-five years is that I have to sell what the public like, and not what I like. This I take it is to a great extent the reason of the success of most businesses outside our own profession—the difficulty is to find what the public like.

For some years now I have made it part of my duty—in fact, place the expenses in my books as business expenses—to attend each year the autumn photographic exhibitions; there is something to be learnt from them, but so far I have not learnt that the public will purchase what they do not want, nor have I learnt that it is my province to educate the public and neglect my duty and throw my family on the parish.

Liverpool.

A COUNTRY PROFESSIONAL.

[The writer of the review in the "Times" appears to overlook the aim of the present exhibition, which is to allow photographers to compare their work with that of others, and for the worse to learn from the better. Regarding our correspondent's speculation as to the identity of the writer, we may point out that precisely the same review, unacknowledged to the "Times," appears in last Tuesday's "Amateur Photographer."—Eds. B.J.P.]

#### PHOTOGRAPHIC RESEARCH.

To the Editors.

Gentlemen,—I am much obliged to Mr. F. A. Bridge for his explanatory letter, but I must point out that I did not make an quotation from the conditions. I referred to the second condition, its entirety, without quoting it either in part or completely, so Mr. Bridge's amendment of the quotation I did not make has involved waste of good and useful italics. I am glad to learn that no obstacle is to be put in the way of the experimenter, but in this case I find to see why any special reference to permanent apparatus need have been made. The first condition requires "a general statement of the way in which it is proposed to expend the grant," and the second condition, read in the light of Mr. Bridge's letter, seems unnecessary. It is, I still think, likely to deter applicants, and, moreover, it raises the question of what is permanent apparatus. I take it that even a test tube may be classed as permanent apparatus until it is broken, while a camera is more or less impermanent in some hands.

The reason for the reservation is by no means obvious to me though Mr. Bridge seems to consider it should be so.—Yours, etc., Blackheath, S.E. C. WELBORNE PIPER.

CORRECTION.—A misprint in a reply to a querist last week may have misled some unacquainted with patent law. A reader asking us if the home manufacture of adhesive tissue was an infringement of the Adhesive Dry Mounting Co.'s patent, should have been told that it was. The company, we understand, have taken steps to protect their patent rights, and are prepared to proceed against those who employ tissue not of their manufacture.

THE Photographic Convention.—Owing to the great success of the last "social evening" another is to be held next January on the same lines. A special committee has been appointed for this affair matters connected with the Hereford meeting (as last year) consisting of Messrs. Alfred Ellis, E. J. Ward, Walter Potter, H. Snowd Ward, and George E. Brown.

CATATYPE Printing Papers.—Referring to our note in last week's "Summary," the Rotary Photographic Company inform us that "Catatype" printing, as a commercial process, will shortly be heard more of. The company has taken over the English patents, and as soon as a certain amount of still necessary experimenting is complete, the process will be placed on the market.

A SPECIALTY.—According to a morning paper, a photographer in London is taking portraits in a new way. He poses his subjects sitting by the fire, and reproduces the scene with all the cosy glow of a drawing room in autumn, before the electric lights are switched on. The photographs are costly, but a bill of something like seven guineas a dozen does not dismay the woman who admires originality.

PHOTOGRAPHING Fortifications.—The "Echo de Paris" reports that the judicial authorities have been informed of another affair of espionage. A Bavarian artillery captain, who said he was Captain K., of the 11th French Artillery Regiment, and pretended that he had been sent on a tour of inspection, last summer succeeded in penetrating the forts and batteries of the north, and taking photographs there.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

H. Williams, 70, Cross Roads, Elvedon Estate, Suffolk. Photograph of a Hall stand made of Brass Cartridge Cases.

E. Pickup, 1, Ivy Grove, Rawtenstall. Photograph of the Goodshaw Brass Band.

R. Woods, 11, Eye Bridge Street, Norwich. Photograph of Mr. and Mrs. Potter.

Lacroix, 111, Hallam Street, Portland Place, London, W. Photograph of Mr. Carl, in front of Empire Theatre, Leicester Square, with four of his bills.

A. Careton, 2a, Bells Arcade, Burnley, Lancashire. Photograph entitled:—"Three Orchids."

John A. Bradbury, 5, Cathedral Yard, Manchester. Two photographs of the Rev. C. Harpur.

A. Hanson, 3, St. James' Street, Guernsey. Two photographs of the Guernsey Fire Brigade.

A. W. Isenthal, 85, Mortimer Street, W., and O. Sichel and Co., 32, Bunhill Row, London, E.C.

**MICRO-PHOTOGRAPHS.**—A reader of the "B.J." I would esteem it great favour if you would kindly give a little of your valued assistance. I wish to try my hand at making a few micro-photographs. The "B.J." ALMANAC, 1899, page 365, gives some directions. (1) Can you tell me if collodion cotton in 2nd formula is pyroxylin, if not what it is? (2) Also what is meant by ammonia in the 3rd formula? (3) Should also be very grateful if you know of any further hints on the production of micro-photographs, or if I could obtain any further literature on the subject. (4) Can you tell me where I can obtain the small cylindrical pieces of glass they are mounted on?—F. G. PERKINS.

1. Yes, ordinary pyroxylin; that made at a high temperature is best for this purpose. 2. The ordinary liquor ammonia of commerce. 3. There is no work published on the subject. 4. At any of the opticians who make a feature of the materials used by microscopists, such as Beck's, Cornhill; Baker's, High Holborn.

**RETOUCHING VARNISH.**—Mr. A. Whiting gives a retouching wrinkle on page 701 of "B.J." ALMANAC for 1906, in which one of the ingredients is 40 ozs. of alcohol. Can you kindly tell me if the "alcohol" referred to is ordinary methylated spirit, alcohol 838 deg., or absolute alcohol? Will ordinary methylated serve?—WILLIAM ERNEST.

The ordinary methylated spirit of commerce will answer practically as well as pure alcohol.

**RETOUCHING.**—(Reply to Miss W. S.).—Remarkably good for the very short time you have studied. We have had far inferior specimens from retouchers who have been many years in professional employment. You have texture, softness and exceptionally good preservation of the likeness. Be careful not to work too closely on old faces, and with large heads draw back a fair distance compared with your range of vision for the smaller subjects. If fairly quick in attaining your effects you should have but slight difficulty in securing a situation with a

high-class firm; but quickness does not usually come in ten months.

**SAFE LIGHT.**—Can you give us a formula for solution of "safe light" for use in tank dark room lamp? Saturated bichromate of potash is unsatisfactory.—SAFE DARK ROOM LAMP.

A mixture of tartrazine (2 part) and rose bengal (1 part). The addition of the latter dye to the bichromate would render the latter safe, but we think the two dyes by themselves are better.

**STAGE SCENES.**—About what would be the exposure for a scene of a theatre light as it would be for ordinary stage lighting (no people in the scene). 12 x 10 plates about 200 H and D. 11in. focus lens at f/8?—ENQUIRER.

You might try 10 seconds as a preliminary. Certainly a highly orthochromatic plate will give much better results. A bathed pinachrome plate would be advisable. You may turn with advantage to the article on the subject by Mr. Arthur Payne in our issue of July 6.

**HYPERFOCAL DISTANCE.**—Kindly inform me what is the hyperfocal distance of a lens of 7.08 inches equivalent focus when the circle of confusion is 1-100 of an inch.—T. B. C. W.

The hyperfocal distance is equal to the focal length multiplied by the diameter of the aperture and divided by the diameter of the circle of confusion. As you do not mention any particular aperture we cannot fully answer your question, but if you divide 418 feet by the aperture number you can arrive at the answer. For f/8 the distance will be about 52ft., and for f/11 it will be 38ft.

**CARDIFF.**—We have not seen the apparatus, and from your description do not see how it acts. If the lens is placed directly over the sitter's head it cannot be used, so far as we see, for throwing a shadow on the easel. If what you want is a method of projecting the image of a person on to a surface we can only say that it would be an extremely difficult thing to accomplish. The sitter must be very strongly illuminated, and there must be an optical projecting system between him and the surface. Very few details would be discernible excepting in a darkened room.

**BLACK SPOTS ON P.O.P.**—Will you inform me (1) the cause of tiny black spots in the P.O.P. paper? I am frequently troubled with it. I have had over thirty years' experience with our own prepared albumenised paper, and therefore know very little of the working of the P.O.P. (2) How often do you make a new toning bath? Ought it to be filtered occasionally? (3) Is it the fixing bath the cause, as I see it is a yellowish tint? (4) How long is it necessary to keep the prints in the hypo? Is five or six minutes sufficient? (5) What is the best mountant? I find the corners come up after passing through my hot burnisher. Is there no mountant sold ready for use? I always used gelatine, dissolved, but I find the hot burnisher makes it blister. (6) I have filtered the toning bath, still I get the tiny black spots. I remove them with a fine pointed needle, but it is a lot of trouble. Would you advise the toning bath made with distilled water or boiling water, then add the gold, etc., when cold?—J. S.

(1) Black spots are almost invariably caused by metallic particles, such as rust, in the first washing water, and they can be entirely prevented by immersing the prints, without previous washing, in salt 2 ozs., water 20 ozs., for five minutes, then washing and toning. (2) Our correspondent does not state what bath he is using, but the correct way is to make up the bath and apportion it out, so as to allow a given amount of gold to a given area of paper, and not to use it for more or again. There is thus no necessity to keep any quantity. (3) The black spots rarely appear in the fixing bath. (4) The duration of fixing depends to some extent upon the temperature, but certainly ten minutes should be allowed, and fifteen are better. (5) The question of mountant is to some extent a matter of personal taste, but any dextrine mountant is, as a rule, satisfactory, and can be obtained from most dealers, and a formula will be found on page 984 of the ALMANAC for 1906. (6) The use of distilled water is preferable, but not essential; if the sulphocyanide bath is used boiling water should be used, the gold

added to the hot sulphocyanide solution, and the bath is fit for use as soon as cold.

**COLLODION PRINTS.**—I should be very much obliged if you could assist me out of a very (to me) serious difficulty. I am using a C.C. paper, toned in gold and platinum bath as follows:—Water, 30 ozs.; borax, 120 grs.; gold,  $\frac{1}{4}$  grs.; an hour before use. Prints are quickly rinsed and put into: Water, 35 ozs.; phosphoric acid, 160; platinum as required; quickly washed, then to fixing bath for twelve minutes; hypo, 1 part; water, 15 parts; two hours' washing, then mounted at once, using starch, and spread out to dry till next morning. About three or four days spots and streaks appear. When first using the paper (about two months ago), I got the same sort of spots, and in writing to the makers they put it down to me putting the wet mounted prints between blotting-paper under pressure. Since then I have spread them out and left to dry all night, and still the spots appear in a few days time. I am most reluctant to give up the use of the paper, without making an effort to get at the cause of the markings, hence my appeal to you.—SPOTS C.C.

The spots are probably caused by the mounts not being perfectly dry after prints have been attached. The mounted prints should be stood up on a rack, so that air can circulate round back and front of them. Prints should be dried as quickly as possible; slow drying is a cause of these yellow spots. Have you read the correspondence and articles on this very subject in "B.J." for November 10, November 17, and November 24 last year?

**JEWELLERY LICENCE.**—In common with other photographers, we are selling a number of pendants, complete with photographs. We never heard of a photographer having a licence for selling plate; is it necessary for selling 9-carat gold pendants? We look for answer in your "Answers to Correspondents."—H. AND CO.

No licence is required if the article is under 2 dwt. Above this weight a licence is required, and costs as follows:—Above 2 dwt. and under 2 oz. (gold), £2 6s.; above 5 dwt. and under 30 oz. (silver) in one article, £5 15s.

**DRYING BOX.**—The plates should be racked vertically, or nearly so.

**CANVAS.**—Griffith's Steam Works, 26-31, Eyre Street Hill, Hatton Garden, London, E.C.

**J. B. (Manchester).**—The agreement, a copy of which you enclose, is one of the most extraordinary, if not the most extraordinary, we have ever read. Why anyone should sign such a one to obtain twenty postcards of himself passes our comprehension. Whether such an agreement would hold good in a court of equity we very much question. This is a question, however, that you had better refer to your solicitor, as it is beyond our ken.

**ANTI-EXPORT.**—Any leading firm of enlargers will make you platinum enlargements on silk or satin. A bromide satin is also on the market.

**DISTEMPER BACKGROUND.**—Would you kindly inform me what colours I should require to paint a background in distemper (I wish to paint in black and white)? Also, would you inform me if there is a text book on background painting, and, if so, where could I get it?

Mix common whiting and "drop black" to the tint desired with water, to the consistence of thick cream. Then add double size of the oil shop (melted and quite hot), in sufficient quantity to form a thin tremulous jelly when cold. No precise quantity can be given, as the size varies so much. Allow to get quite cold. The colour should be applied cold with a large whitewash brush, and quickly, so that all is covered before any portion begins to dry. No portion should be gone over twice, or marks will show. The canvas should be sized before the colour is laid on. There is no work published on the making of backgrounds.

**L. M.—1.** We should choose the A lens for better covering power and shorter focus. **2.** The A lens would answer well, but we take it you want a lens of slightly curved field, in which case one of the old double lenses should suit you. See under "Ex Cathedra."

**ARTIFICIAL LIGHT.**—1. Are mercury-vapour lamps for portrait studio as good in every way as arc lamps? They seem cheaper in every way to run. **2.** Will mercury-vapour print platinotypes as satisfactorily as if done by daylight? Are they as good for enlarging as the usual light with denser? The method of using them is, I think, to put on one side of a box, painted white inside, the negative to be enlarged by a reflected light, the lights themselves to be invisible lenses. Will you be good enough to give me any objections of these you know of? **4.** Also, I find in this town, they only allow me to put these lights for printing and operation at the lighting rate of fivepence per unit, and not a power of 1½d. per unit. Is this usual in other towns? I should consider it a "daylight body," and, therefore, power 1½d. per unit.—A. M.

1. Portraits equal in every way to those taken by lamp may be produced by the mercury-vapour lamp. Some large enclosed arc lamps are of greater candle power, and may or may not imply increased efficiency for portraiture, depending on the conditions of working and the requirements. Platinotypes may be printed by the mercury lamp, which is indistinguishable from prints made by daylight. 2. Mercury tubes may be used for enlarging, and are so used by the largest firms of trade enlargers. The tubes are behind the negative, the light being equalised over the negative by a sheet of opal glass, or several sheets of ground glass. This method is preferable to that suggested in the query, exposures being shorter. **4.** We believe it is quite usual for supply companies to charge on a "power" basis for electricity consumed during the day time, but circumstances may vary. We know of no objections to the mercury lamp other than the peculiar colour it gives to the flesh, and this is quite easily come by the use of a cluster of half a dozen ordinary incandescent electric lamps.

**THE Action of the Levy Screen.**—In reference to the statement announced by Mr. Howard Farmer as that of his inaugural address to the students at the Photographic School at the Regent Polytechnic, Messrs Hunters, Limited, write to us from Poppin's Court, Fleet Street, to the following effect:—"We are glad if you will allow us to say that any results that can be obtained by the use of the Levy screen, either for process or professional lithography, would apply equally to the Haas system for which we are the sole agents. The Haas is guaranteed by us to be equal in every respect to that of the Levy make, and is sold with this guarantee. Further, that we are willing at all times to send these screens on approval, to be tested against the Levy system, and that in the majority of cases we are able to offer equal size ruling on more advantageous terms."

**THE Sefton Park Photographic Society, Liverpool,** announce an annual exhibition, to be held at St. Barnabas Hall, Smithdown Road, from November 20 to 24. The judges will be the Rev. H. W. Dickson and Dr. A. T. Lakin.

\* \* \* **NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## The Hyperfocal Distance.

The Lumières have examined the action of formaline on gelatine and find that the action increases with the strength of the solution to 10 per cent., and that long treatment with hot water renders the gelatine soluble again. (P. 866.)

cable in the case of metric measures. He explains that the hyperfocal distance in metres exactly equals the focal length multiplied by the diameter of the aperture in centimetres, one-tenth millimetre being the diameter of the circle of confusion. This is hardly such a convenient rule as the one applied to English measures, for the diameter of the aperture is seldom known. In his examples Dr. Johnson resorts to the division of the focal length by the aperture ratio number in order to ascertain the diameter, and we must point out that it would be simpler to include this operation in the formula. We should revise this second rule as follows:—The hyperfocal distance in metres is equal to the square of the focal length in centimetres divided by the stop ratio number.

\* \* \*

**Approximate Infinity.** In our issue for August 24 we gave the rule for ascertaining the distance of approximate infinity as follows:—"The correct method of arriving at a minimum distance of approximate infinity is to first decide on the maximum permissible displacement of the image, and then divide that amount into the square of the focal length. The result is the extra focal distance of the nearest object that may be considered to be at an infinite distance." Dr. Lindsay Johnson (in his article previously referred to) makes the remarkable comment that this formula unfortunately "omits entirely one of the chief factors of the problem, viz., the ratio aperture or intensity of the stop." In our paragraph we referred to the confusion that exists in regard to the matter of infinity, and we hoped that our note would help to clear things up. It would, however, appear that our effort was a failure if Dr. Johnson was left under the impression that aperture affected the question. It is, of course, quite impossible for it to do so at all, and Dr. Johnson has confused the minimum distance of approximate infinity with the hyperfocal distance, which is an absolutely different thing. That this is his error is manifest from his confused and altogether erroneous definition of hyperfocal distance as "the distance at which the nearest object may be considered to be in the same focal plane as an object at infinity." There is, as a matter of fact, a very big difference between the distance of approximate infinity and the hyperfocal distance. When we focus on the former distance the plate is practically placed in the principal focal plane of the lens, but when focussing on the latter the plate is a considerable distance behind. Two-twentyfifths of an inch in the case of  $f/8$ . and a circle of confusion of 1-100 in. If we allow a displace-

ment of the focussing screen to the extent of 1-100 in the one case, and a circle of confusion of 1-100 in. diam in the other, the minimum distance of approximate infinity is, roughly, a little over eight times the hyperfocal distance for  $f/8$ . Indeed, we may adopt Dr. Lindsay Johnson's approximation and say that, while the hyperfocal distance in feet is the square of the focal length in inches the distance of approximate infinity in feet is eight times the square of the focal length in inches. If, however, we wish to find the principal focal plane of the lens, 1-100 in. is far too big an error. We must then allow 1-1,000 in. only, and this increases the distance on which we focus to no fewer than eighty times the hyperfocal distance for  $f/8$ .

\* \* \*

#### Definition of Hyperfocal Distance.

As before pointed out, Dr. Lindsay Johnson defines hyperfocal distance wrongly in his article, while in the heading of the article he adopts the popular but very misleading description, "Distance beyond which everything is in focus." It has been pointed out by numerous authorities from time to time that this definition is only true when we focus on infinity, or when the plate is at the principal focus of lens; and, as such a method of focussing is seldom, if ever, adopted for anything but astronomical or telephoto work, the definition is of little practical use. There are really two distances that are called hyperfocal distances. One of these distances is the near limit of the depth of field when we focus on infinity, and the other is the distance on which we should focus to obtain the greatest depth possible. The difference between these two distances is only one focal length, hence they are commonly considered to be the same, and the term hyperfocal distance is applied indiscriminately to both. The second one is the distance of greatest view to the photographer, and the lenses of fixed-focus cameras are usually so adjusted as to render this distance sharply. All objects beyond half the hyperfocal distance are then in focus, so it is obvious that the idea that objects beyond the hyperfocal distance are in focus in practical work a misleading one. The formulæ by which these hyperfocal distances are found are the same, but one expresses a nodal distance, and the other an extra-focal distance, the limits of the distances are separated by focal length. It is interesting to note that it was experience gained in setting hand camera lenses that induced many practical men to deny the truth of the theoretical dictum that depth is solely a function of focal length and aperture. It was found that some lenses could be set

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1907.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-sixth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,616 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1907 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### THREE-COLOUR PHOTOGRAPHIC PRINTING PROCESSES,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1907 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1907 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—Our publishers ask us to inform Agents that it will be as well to place their orders for copies immediately, as the issue is always booked before publication, and a second edition will not be printed.

aid of calculated tables of hyperfocal distances while  
could not, and, in spite of the derisive remarks of  
the practical individuals had solid reason for  
saying that depth varied with constructional details of  
objective. The theorists also are now convinced of the  
fact, and it is advisable for every one to understand  
calculations relating to depth are not always trust-  
worthy.

\* \* \*

With the advent of late autumn and  
winter we have a distinct drop in the  
temperature, and at the same time an increased number of  
fogs on which the atmosphere is more or less charged with  
moisture. These two conditions, and particularly the  
fog, tend to retard the drying of negatives, and this  
is the time which is in many studios the busiest of the year—  
the Christmas rush. Not only does this slowness of dry-  
ing prevent the prompt sending out of proofs, but it may  
cause markings in the negatives which are ineradicable,  
if they can be removed, require a great deal of extra  
work from the retoucher. Such marks, it is true, are  
likely to occur when the atmosphere is very humid  
and the temperature mild, the sort of weather we have had  
on several occasions during the past month. As might be  
imagined, we have been shown a number of negatives  
marked with small pitted markings, either in patches or  
over the film, and we have had no difficulty in deciding  
whether such pits were the result of either an unnecessarily  
soaking in a washing tank of large size, the water in  
which was not completely changed with sufficient fre-  
quency, or the too slow drying in a muggy and more or  
less impure atmosphere. The gelatine had acted as a  
culture, the prolonged time of drying giving sufficient  
opportunity for considerable growth. The washing should  
be completed in an hour in running water, and if the  
negatives are passed through a 1-20 bath of formalin it  
not only hardens the gelatine and admits of drying in a  
cupboard, but, being an antiseptic, it more or less  
kills any bacilli which may be in the gelatine.

\* \* \*

We are much obliged to Mr. Bennett for  
his letter and formula on pages 857-8.  
A comparison of his formula with ours  
with Mr. S. A. Herbert's is interesting. Mr. Bennett's  
formula only  $1\frac{1}{2}$  grains pyro per ounce, while ours has  
4 grains and Mr. Herbert's has 4.4 grains. In the following  
comparative table we have diluted these two strong  
formulæ until the amount of pyro is the same in all three.  
These formulæ are thus much weakened, and ours, at  
least, will not produce in this diluted form anything  
nearly so fair printing density in the time that Mr. Bennett's  
is sufficient for his formulæ:—

	B. J. Formula. A.	Mr. Bennett's. B.	Mr. Herbert's. C.
Pyro .....	$1\frac{1}{2}$	$1\frac{1}{2}$	$1\frac{1}{2}$
Soda bisulphite...	2	$1\frac{1}{2}$	$1\frac{1}{2}$
Sulphite .....	$8\frac{1}{2}$	12	9
Sulphate .....	$16\frac{1}{2}$	12	18
Bromide .....	—	$1\frac{1}{2}$	—
Water .....	1 oz.	1 oz.	1 oz.

It will be noticed that A and C are remarkably alike, and  
we may assume that these two, in the diluted form,  
behave similarly—that is to say, both are exceptionally

weak developers that require a very long time to produce  
sufficient density. A would, we know, not produce what  
Mr. Bennett probably considers a fair density unless we  
prolonged the time to something well over twice the time  
he finds sufficient. Yet his developer contains less car-  
bonate, and more sulphite, and is restrained with bromide.  
At first sight most people with practical experience of  
development would assume that A and C must act much  
more rapidly than B, whereas B is something between  
twice and three times as active as A. There is evidently  
a problem here that it is desirable to solve, and we hope  
to be able to take up the subject shortly and endeavour to  
clear up the mystery.

\* \* \*

### One-Exposure Colour Photography.

Sir William Abney, in exhibiting his  
three-colour projections of landscapes at  
the Royal Photographic Society's exhi-  
bition on Thursday in last week, remarked on the need  
of a one-exposure camera when the sky contained many  
moving and brightly-lighted clouds. He exhibited several  
examples of the coloured shadows caused by the movement  
of clouds between successive exposures. In dull weather,  
or under an unclouded sky, this disability of the succes-  
sive exposures is not encountered, and Sir William pointed  
out that it would be no inconvenience in the case of re-  
composing the colours as paper prints instead of by the  
Ives projection method, which he employed. Dr. Miéthe,  
we are also interested to see, has been doing a good deal  
of one-exposure colour photography of panoramas seen  
from a balloon, for which work, of course, it is the only  
method. Miéthe uses a three-lens camera, with the dia-  
phragms of the lenses adjusted to give the equivalent ex-  
posures required by the screens. He employs a focal  
plane shutter, and, with ethyl-red bathed plates, finds an  
exposure of one-tenth of a second sufficient. A reproduc-  
tion of one of his balloon photographs in colours accom-  
panies the current issue of "Das Atelier."

### Sales at the Exhibitions.

The record of the year, or, we believe,  
of any year, in sales of a single picture  
at the two London exhibitions is made by Mr. S. G. Kimber  
at the Salon, where no fewer than thirty-one copies of  
"A Sunlit Cloister (No. 117) have been sold. It is a  
curious fact that at an exhibition where the most extreme  
examples of the "unphotographic" are to be found, this  
large number of purchases should be made of a picture  
which in its effect, no less than its method of production,  
represents photography free from hand interference. No  
doubt the explanation of this apparent anomaly rests  
firstly with the great difficulty of duplicating works that  
are due to handwork, and secondly with the higher prices  
such works must necessarily command. We understand  
that Mr. Kimber considers the execution of his orders  
quite task enough and by no means a liberally paid one.  
Next to Mr. Kimber comes Mr. Cavendish Morton with  
four sales of "Fantasia" (No. 181), and, in addition to  
these, there are but thirty-three other pictures sold. At the  
Royal, too, Mr. Kimber heads the list with four sales of  
(No. 100) "A Relic of the Past." His total receipts amount  
to the respectable sum of thirty-five guineas, not a bad  
return for his London exhibiting. The total sales at the  
Royal reach the sum of £35 5s. 7d., which is considerably  
under that of previous years; but in this connection it  
must not be forgotten that the R.P.S. has now given up  
its old practice of purchasing to something like the sum  
of £20 a year. Moreover, the prices upon the New Gallery  
exhibits are this year particularly modest ones.

### A Shop Window Attraction.

It has fallen to the proprietor of a New York cigar store to show photographers a most ingenious application of their own art to modern street advertisement. The cigar store in question, so we read in the "Photographer," displayed a notice in its window that pictures of the people looking into the window would be taken and the prints shown inside. Those identifying their portraits in these prints were given a free box of cigars. The windows were handsomely dressed, and hidden behind figures here and there were cameras and the operators. Every now and then a small box of cigars covering a lens would be drawn up on a string and an exposure made. Of course, everybody was pushing to the front to see the fun, and incidentally to have their pictures taken, for the desire to perpetuate one's features is inborn. Some of the prints were daily pasted on the windows to show what was being done. The idea could very well be taken up by an enterprising photographer who is looking out for the cheaper class of trade.

\* \* \*

### Part Payment at the Sitting.

We suppose there is no more widespread grievance—next to the refusal of the management of the BRITISH JOURNAL to bring out the issue twice a week—than the practice of customers who have been photographed and had proofs submitted to them, of taking no further notice of the photographer, but straightway handing the prints over to a cheap copying firm or amateur friend for further copies, or availing themselves of the offers of religious papers to supply a £2 2s. enlargement for 4s. 6d. This question came up in the recent conference of the National Convention of Photographers of America at Niagara Falls. One speaker stated that it was his custom to charge a fixed deposit fee of one dollar, but that practice, in the opinion of another photographer, could not be advised as an invariable rule. It was his custom to introduce the question of deposit casually, and to lead the customer to ask the amount. In the case of a lady he would then allow her to fix the sum at whatever suited her. The opinions of other speakers amounted in the aggregate to the view that the photographer must know his public perfectly, and act according to his knowledge in giving credit or in enforcing payment. As the views of one or two speakers seem to be worth reporting at length, we find space for them on another page.

### WARMING THE STUDIO.

THE approach of winter must probably lead many photographers to give some thought to the heating of their premises with a view to improving their present arrangements as regards efficiency and economy. The preservation of a comfortable temperature in the rooms used by the public or by the photographer's workpeople is a matter of first importance, for customers cannot be expected to prove good sitters in an apartment which strikes them as chilly, and, as to the assistants, money expended on their comfort is well laid out, according to the experience of both large and small industrial concerns. In our remarks, however, we shall refer more particularly to the studio itself, since it is the apartment in the photographer's house least amenable to easy warming.

It is not like an ordinary room to keep at a genial temperature, as the area of glass which enters into its construction, although a non-conductor of heat, is quite different from a brick building, and, furthermore, the laps of the panes, as a rule, are not filled up and much of the heat, therefore, escapes between them and is lost. Hence

it will be seen that the conditions of warming a photographic studio are not the same as in the case of an ordinary room.

There are several systems by which studios and rooms can be heated, and they all have their advantages, but most of them are accompanied by disadvantages, well as more or less serious inconvenience, and we prefer here to refer to some of them so that those who are undecided on their heating arrangements for the winter may get some idea as to which will best suit their requirements.

Hot water pipes, such as are employed in heating cultural buildings, with the boiler placed outside the building, are probably the best system of all, as the pipes may be laid through the studio and through workrooms on the same floor, so that all are warmed by one fire. This arrangement there is no dust anywhere; with most of the others dust is a great nuisance. The hot water system is very economical in so far as the consumption of fuel is concerned, and by keeping a small fire under the boiler during the night it will require no attention; the rooms are always kept at a genial heat. A drawback to the system is that the fire must be started, supplied, and that it has been allowed to go out, some time before the fire is required, as the warmed water but slowly circulates through the pipes. Another disadvantage is that in very severe weather the fire must always be kept burning, otherwise there is a risk of the water freezing in the pipes at the most exposed portions, and when once this happens it may be a long time before they become thawed again. If the fire were lighted while they are in the frozen state there would be a danger of the boiler exploding. Another drawback to the hot-water system is that it is somewhat costly to instal in the first instance, but, as just stated, it is about the best, and the most economical in the long run, particularly when several rooms have to be kept warm. There are hot water arrangements suited for small studios, servatories, studios, and the like, in which the boiler is heated by gas, which is easily regulated. These have the advantages of the larger installation, but are applicable where small spaces have to be warmed; furthermore, the gas is more costly than when other fuels are used.

Then we have gas, *per se*, as a heating medium. It is cleanly and conveniently under control, and inexpensive to instal; in addition, most of the gas companies let heating stoves on hire at a very moderate rental. One of the chief drawbacks to the use of gas stoves for heating purposes is that, unless there is a flue to carry off the fumes the latter become unpleasant, and are injurious to health when one is continually in them. If there is a flue to carry them away it also carries off much of the heat in which case gas, while so very convenient, is not so economical. Without a flue all the heat is used up and gas is not expensive to employ.

There is a form of gas stove that requires no flue, yet gives off no fumes, but it, unfortunately, gives off but little heat and is only suited for rooms of large dimensions, such as small offices and the like. Last winter we were in a studio of medium size that was warmed by a gas stove called the "Chancel." It is a flat stove on the floor, on a stone slab. All the products of combustion are given off in the place, but they are not so unpleasant if a good sized tray of water be placed before it to absorb a good portion of them, much of the remainder escaping through the laps of the glass in the roof. The stove is not an expensive one, as its cost is, we believe, something like a pound, or less. It is made by the Electric and Gas Company, and is designed for heating churches and similar purposes.

A type of stove which will commend itself to many as the heating the studio is known as the slow combustion stove.

the forms and names are legion. They are very economical in use and require but little attention. Some are entirely closed, and some are semi-closed so that the visible fire gives the place a cheerful appearance. Coke, or anthracite coal, is the fuel best suited to the latter kind. They throw out a good heat, which, like the consumption of fuel, is regulated to a nicety by closing the damper. If the stove is filled in the morning it will last the day without attention. If the fire is made up at night, and the damper nearly closed, it will last the night through or, indeed, from Saturday till Monday if very little draft is admitted. These stoves are very ornamental while not at all costly. The closed stoves are generally less in price, while the most for fuel, coke and coal, is much about the same. They, like the other form, require but little attention, and the heat is similarly under control. A medium size one, plain, not ornamental, is sufficient to keep a studio about twenty-five feet by eleven feet at a comfortable temperature, and costs only about a sovereign, or perhaps a little more. Those who propose to adopt this form of heating would do well to get the illustrated price lists of makers of this type of stove, such as Smith and Wellstood, of Ludgate Hill, and others. As regards cost of running we may perhaps give our experience of one used day and night in a large room of our own, which consumed less than two shillingsworth of anthracite per week. This type of stove, of course, requires a flue to carry away

the smoke. If there is a chimney adjacent it can be connected with that, but if not it must be conducted through the roof of the studio, in which case it is desirable to have as much pipe within it as convenient, say by carrying up on a slant instead of vertically, as then more heat is utilised, as much passes along it and is diffused through the building.

The principal drawback to these stoves is that the combustion is so perfect that the fuel is consumed to a very fine ash, and when cleared away *carelessly* becomes diffused throughout the place and settles on everything, unless care is taken to damp it before it is removed. Should any of this dust, which is charged with more or less sulphurous matter, happen to settle on silver prints while they are moist the particles will most likely produce spots. Another drawback to pipe stoves is that the insurance companies have an objection to them, and if one is fixed without notice being given them the policy will be invalidated. Hence, if a fire occurred on the premises, although the stove or its flue had nothing to do with it, the policy would, nevertheless, be null and void. It is usual in granting a policy for premises where there is a pipe stove to state the length of pipe, and that the latter must not be increased without notice to the company, otherwise the policy will be invalidated. Makers of stoves, such as Messrs. Wellstood, will, however, erect stoves to satisfy insurance companies' conditions.

## PAYMENT AT TIME OF SITTING.

THAT debateable subject, the payment of a deposit at the time of the sitting, occupied a large share of the discussion on reception room methods at the recent convention of professional photographers at Niagara Falls. We extract one or two of the views expressed by the speakers from the columns of "The Photographer" (New York).—Eds. B.J.P.

Mr. Holden said: We are compelled to consider our environment. A person comes to me and says, "Mr. Holden, I should like to have some pictures made." Very good, I commence to work and find out just what she or he wants, and the work may be done without any previous entry being made. They say sometimes, "I would like to have some pictures made. I want you to make them, and I want you to use your own judgment." I don't at once take them and say, "What kind do you want?" I go in and use my own judgment, as they have given me the privilege of doing so. Then when I go through they often come to me and say, "How much deposit, Mr. Holden?" "Just whatever suits you," I reply. These are my own personal experiences. "Just whatever suits you." They are my neighbours, and I want to keep on good terms with them. I don't want to give them a hammer blow right on the first start. After a little time a customer will drop in, and the usual routine is gone through, and I know them very well. We get into a little chat and a question of payment is forgotten. There is where the man and his bigness begins. Don't say, "I won't finish that proof, because there is no deposit paid." I have seen the equal of that in the years of my experience. But I believe every man to be honest, and I believe every man is honest if you will give him an opportunity to be so.

### The Business System.

Mr. Wilson: My method in regard to that is this: In my community I believe I know nearly everybody. I let the reception room lady or gentleman, about whom we have heard so much, handle them. She has her instructions to collect at least one-half. The question is, "Would you like to pay a half of this?" The proofs come in the morning. When they pay their half they get a little ticket with the stub, and they come up to the composing room on the next floor above. The operator takes the stub, and they keep the card with a number marked on that card, and when the proofs are finished the next day they are put in an envelope and the name is put on, and "deposit, so much due." When they call or send they are told that it is Mr. Wilson's custom, and you are

expected to comply, and they usually do. In a case where they haven't come up, they simply don't give them the proofs. It being a luxury, they generally provide themselves with the money for making the deposit. I believe in not arguing too much on re-sitting. Try and get a good result in the beginning, regardless of the intrinsic cost, and then, if they are reasonable about it, try and be likewise.

### To Prevent Loss from Unfilled Orders.

Mr. Goldensky: I have two assistants. I have two classes of people—the average man and the women with fine dresses who have plenty of money, or pretend to have plenty of money. I have various prices. For instance, in a four-dollar picture I insist on having a half deposit, two dollars, and when I send out the proofs there is a printed note, which reads that after the proofs are satisfactory and they return the proofs by mail or person, they have to settle the amount of the bill. If for any reason the proofs are not satisfactory, they are welcome to call at the studio as many times as they choose until they are satisfied. That gives them the privilege, only they pay two dollars, and after the proofs are sent, if the proofs are satisfactory, they know they have to pay the other two dollars. The reason I establish that rule is this: Every year I used to find in my drawers and in the closets three or four hundred dollars' worth of work that was never taken out, but simply left for various reasons. A person gets engaged to a young lady, and he goes to a studio and sits for pictures; by the time the pictures are finished the engagement is broken, and those two dollars are left in your drawers. He will never take them out. (Laughter.) A person works in a shop and comes in and pays two dollars deposit. He orders pictures; in the meantime he loses his position or takes sick. He cannot afford to take those pictures out, therefore you lose him as a customer, and you lose that out of your money profit.

### Adjust your Method to your Class of Business.

Now, speaking about the better class of people. There are two distinct temperaments among them. One will come in and say, "Mr. Goldensky, how much deposit?" "It is optional to you

You may leave it or you may not." "I'd better leave it." Those are the people that will pay the bill quicker than you can send the pictures. Another class of people will come in who will not look at your receptionist. "Where is your dressing room?" After you have made your sitting and most politely ask whether it is convenient for them to make a deposit (applause) they say, "Is it necessary?" "It is not necessary, but customary." Or "if you are not ready to pay it now, you can do it after you return the proofs." It gives them a nice hint that when they return the proofs they must pay the deposit. Then on the proofs, when we send them out, I put a little note, that these proofs are the property of Elias Goldensky's studio. Unless returned within thirty days a charge will be made for labour, time, and material used. I have collected the money. Some people send me in five dollars for a sitting willingly, and they say the opportunity did not come to sit for a picture again, and enclose five dollars for trouble. Certain people, after we send to them the proofs and we do not hear from them, we write to them that if those proofs are not satisfactory, we will be glad to make a new sitting; and if we write one, two, or three letters, and those people are not men enough to send an answer to you, that they cannot come and sit for picture, you do not want their business. It is injurious to you. You might as well send them a bill for five dollars, and if they don't pay it, collect it. You are working for business. I received a letter this morning from my girl in the city that a bill of \$52 was paid. That bill was standing over two years, and never paid. The party is as good as gold, and they travel abroad, and it never worries me. I knew they were slow, but they always paid. Some years ago they contracted a large bill and did not pay it. It never worried me.

You have to size the conditions up, and you have to work on certain lines. Adjust yourself to the conditions. The main thing is, you must interest your public, as a doctor does, as a lawyer does, that you are doing your best work, and you are entitled to compensation. Professional men must be entitled to compensation. If you come to a lawyer and ask him for advice, he sends you a bill for five dollars, and he is entitled to his fee. A person comes into the studio of a photographer, and because it is So-and-So, he uses forty plates, and then the re-sitting comes again and again. It is awfully lovely, and a man sometimes strikes an order; but most of the time he gets

discouraged and disappointed if an order does not follow. There are different grades of temperaments of photographers. One conducts his business on the policy of never send a bill and still make a big business. This does not apply to all of us. If you have got that standard, that you can go with that high class of people, it does not matter whether you lose one hundred or two hundred dollars if somebody doesn't pay. From the ordinary class of people you must collect money all the time.

### Business is Business.

Mr. Herrick: There has been a great deal of talk along the line that photographers want to conduct their business on business principles. When they do that, this man will have no trouble. I started eight years ago, and put a sign in my studio that a deposit was required on all orders, and no pictures would be delivered until all were paid for. I have adhered to that strictly. I have had wealthy men come in and say, "What, a deposit from me?" I said, "Yes, it is my rule; and while I feel I hate to do it for you, I cannot let you off and ask the next one, and that you do not feel that I have confidence in you, if you want \$50 you can have it any day you want it; but if I have to ask your neighbour to pay his deposit I have to ask you." That man says, "I have not got a dollar with me, but I will go down to my safe and get it." It was Sunday. He went and got it. But if a man or woman does come in and gets the negatives made, as this man says, and does not return the proofs, you are a business man or not a business man if you do not send him a bill for making those sittings; and if he don't pay it the law will help you make him pay it. When they have the best of you once, they won't come near you again. I never have a dispute with a customer over anything. If a customer comes in and says, "You have made a mistake; I have paid this," we know whether she has or not, most emphatically, because our books are calculated and kept in a businesslike way; but when this woman says so, I say, "Why our lady must have made a mistake. I am awfully sorry it occurred. We will be careful in the future." It never occurs again. The next time that woman comes we are pretty nearly sure that she knows whether she paid the money or not before she leaves the studio. We should have said words. I am not a photographer. I am merely a business man.

## ON THE TANNING OF GELATINE BY FORMALDEHYDE.

ALTHOUGH it is known that gelatine, treated with formaldehyde or formaline, becomes insoluble in hot water, the composition of the insoluble product has not been determined.

The present experiments were undertaken to clear up the following points:—

I. Is the formalysed gelatine a definite compound of gelatine with formaldehyde, or does it only in all cases contain different quantities of formaldehyde, or does the latter act on gelatine without combining with it, and thus merely changes its composition?

II. If the formalysed gelatine is a definite compound, does this belong to the aldehyde type, or does it possess the properties of an actual compound or those of a simple additive product?

In order to determine whether the formalysed gelatine is a definite compound, formaldehyde of different strengths was allowed to act on gelatine under the different conditions. The tanned products were analysed, after they had been freed, by means of cold water, from any trace of aldehyde that could be washed out,<sup>1</sup> and the results are compared hereafter. As the estimation of the percentage composition of the formalysed gelatine can give no information as to the quantity of the formaline retained by the gelatine, we have proved that it is possible to re-form the formaldehyde from the formalysed gelatine, without altering the formaldehyde or the gelatine, and the former could thus be estimated.

### The Decomposition of the Formalysed Gelatine.

After numerous experiments the decomposition process which gave the best results was found to be treatment in the cold with a 15 per cent. solution of hydrochloric acid. In order to decide the

end of the decomposition, a comparative sample of formalysed gelatine was treated under similar conditions at 60 deg. Fahr., and tests were made from time to time.

If one of the test samples, after thorough washing in water, melted in a water bath, the decomposition was considered as complete. The result was obtained after from twelve to fifteen hours.

The gelatine was then washed by decantation with hot distilled water at 140-160 deg. Fahr., till every trace of acid and formaldehyde was gone, as was proved by Schiff's reaction. The whole of the washing water was then made up to a given volume—with 20 gms. of gelatine, this was 4 litres—and the quantity of formaldehyde then estimated.

### The Estimation of the Formaldehyde.

Several methods were tried for the estimation of the formaldehyde set free from the decomposed formalysed gelatine, and the most satisfactory was found to be that in which the quantity of titrated soda solution with an excess of sodium sulphite solution was observed, which must be added to a solution of formaline, with a few drops of phenolphthalein, in order to produce the characteristic colour of the latter.<sup>2</sup> In a comparative test without formaldehyde, but with equal rights of hydrochloric acid and sodium sulphite, the quantity of titrated soda solution is determined which corresponds to the hydrochloric acid. The quantity of formaldehyde is the result of the difference between the numbers obtained with and without formaldehyde.

<sup>2</sup> Seyewetz & Gibello. Bull. Soc. Chim. In the ordinary process the liquid which contains the formaldehyde and sodium sulphite is alkaline to phenolphthalein; titrated acid is added till the phenolphthalein is decolourised; in this case the solution is acid, for it contains hydrochloric acid as well as formaline.

<sup>1</sup> Till the washing water did not reduce ammoniacal solution of silver nitrate.

As this method was used for a solution of hydrochloric acid, which contained 0.5 gm. per litre of formaline, 0.5 gm. was found.

### Composition of the Formalysed Gelatine.

We estimated the maximum quantity of formaldehyde retained by the gelatine, when the tanning was effected as follows:—A. Tanning of dry gelatine with formaldehyde solution; B. Tanning of dry gelatine with gaseous formaldehyde; C. Tanning of a gelatine solution with a solution of formaldehyde.

A. With the first tanning process we have tested the effect of duration of contact, the concentration and the temperature of the formaline solution.

1. *Action of the Duration of Contact.*—Sheet gelatine was immersed in 10 per cent. solution of commercial formaldehyde solution at ordinary temperatures for varying times, from thirty minutes to five days.

After the removal of the gelatine it was washed in running water till every trace of formaldehyde was removed; then, as already stated, was mixed with 15 per cent. solution of hydrochloric acid and analysed. The results are given in the following table:—

Duration of Contact of 10 per cent. Commercial Formaline.	Quantity of Formaldehyde in 100 gms. of Dry Gelatine.				
	Analysis No. 1.	No. 2.	No. 3.	No. 4.	No. 5.
30 minutes .....	3.6	3.4	—	—	—
12 hours .....	4.5	4.8	4.1	4.6	4.08
5 days .....	4.32	4	4.32	—	—

2. *Influence of Concentration.*—For the same time, 12 hours, the same quantity, 20 gms., of dry gelatine was soaked in an equal volume, 1 litre, of formaldehyde solutions from 1 to 30 per cent. After removal the gelatine was washed, decomposed, and analysed. The results are shown in the next table.

Concentration of the Formaldehyde Solution.	Quantity of Formaldehyde in 100 gms. of Dry Gelatine.				
	Analysis No. 1.	No. 2.	No. 3.	No. 4.	No. 5.
1% Commercial formaline...	3.36	3.6	2.88	2.4	—
5% " " " "	3.3	2.88	3.12	2.6	—
10% " " " "	4.5	4.8	4.1	4.6	4.08
20% " " " "	3.84	4.08	—	—	—
30% " " " "	4.32	4.56	—	—	—

3. *Influence of Temperature.*—An equal volume of 10 per cent. commercial formaline was allowed to act on an equal weight of dry gelatine, at temperatures between 62 and 122 deg. Fahr. The estimation of the formaldehyde in the tanned gelatine gave the following results:—

Temperature of 10 p.c. Formaldehyde.	Quantity of Formaldehyde contained in 100 gms. of solid Gelatine.
62°	4.4
86°	2.8
122°	3.48

B. In order to test the tanning of gelatine by gaseous formaline, a rapid stream of air was passed through a saturated solution of formaldehyde, in order to render that which was carried over damp; the air then passed over dry gelatine.

The gelatine was submitted to this action for varying times, from three to ten hours, and then repeatedly exposed to the air, so as to remove all excess of formaldehyde. Then the quantity of formaldehyde was estimated after every trace of unabsorbed formaldehyde

had been removed by washing. The following results were obtained:—

Duration of Contact of the Gelatine with the gaseous Formaldehyde.	Quantity of Formaldehyde contained in 100 gms. of Gelatine.		
	Analysis No. 1.	No. 2.	No. 3.
3 hours .....	0.96	0.96	—
10 " .....	3.6	3.6	3.52

C. We have studied the tanning of gelatine solution by formaldehyde solution, and used sufficiently dilute gelatine solutions to be able to titrate the excess, immediately after the addition of the formaldehyde—i.e., before the gelatine set.

The titration was made with normal sulphuric acid, after the addition of sodium sulphite, a 2½ per cent. solution of gelatine being mixed with the increasing quantities of formaldehyde. The results are shown in the accompanying table:—

Volume of 14.5 p.c. formaline added to 100 ccs. of 2½ p.c. gelatine solution .....		0.5 ccs.	1 cc.	2 ccs.	5 ccs.	10 ccs.	15 ccs.	20 ccs.
Quantity formaldehyde which combined with the gelatine solution .....		{ <sup>(1)</sup> 1.58 (2) 1.7 }	1.48	1.4	1.8	1.6	1.8	1.66

Above 20 ccs. of formaline the gelatine set, and titration was impossible.

The action of the concentration of the gelatine solution on the combining with formaline cannot be studied, for a gelatine solution stronger than 2½ per cent. sets very quickly after the addition of the formaline, and titration is therefore impossible.

If one tries to produce insolubility of a gelatine solution by adding formaldehyde, a very small quantity of the latter only is required, far less than the maximum quantity which can combine with dry gelatine.

We have actually found that a jelly, which is obtained by the addition of 5 per cent. of commercial 40 per cent. formaline to a gelatine solution, will not again dissolve in hot water when it has once set.

The quantity used thus corresponds to 0.7 to 0.8 gm. of formaldehyde to 100 gms. of gelatine.

There is no doubt that there is here in this case a mixture of gelatine and formalysed gelatine, and the latter surrounds the former and prevents it dissolving, for if the action of the hot water is prolonged, part of the mixture will dissolve.

### The Stability of Formalysed Gelatine in Heat.

We have tested whether the formalysed gelatine shows the stability of a true compound when it is heated to a moderate temperature, or whether it loses formaldehyde easily by heat.

A. *Action of Boiling Water.*—20 gms. of gelatine were immersed for twelve hours at 63 deg. Fahr. in 1 litre of 10 per cent. solution of formaldehyde, then washed in running water till the washing water no longer gave any sign of aldehyde. The formalysed gelatine thus obtained withstands boiling water.

If the boiling is continued for some minutes, considerable quantities of formaldehyde could be detected in the water. If the treatment with boiling water was renewed, it was found that after seven such treatments, formaldehyde was still extracted. The total quantity of water used was about 3 litres, and the gelatine then completely dissolved in hot water, and set when cold.

When the formaldehyde was titrated in all the wash waters the mean was 2.5 gms. to 100 gms. of gelatine.

B. *Action of Dry Heat.*—20 gms. of gelatine, formalysed as in the previous experiment, were, after complete washing, dehydrated with alcohol, and then dried in a drying chamber at 110-140 deg. Fahr. The gelatine thus obtained had no smell of formaldehyde, and withstood boiling water.

We have estimated the formaldehyde in the original formalysed gelatine, and again after it had been heated for three to forty-eight

hours at 232 deg. Fahr. The results are shown in the following table:—

No. of Test.	Nature of Test.	Quantity of Formaldehyde in 100 gms. of Dry Gelatine.
1	Formalysed Gelatine Original.....	4.1
2	" " heated 3 hrs. at 232°F	3.3
3	" " " 12 " "	2.88
4	" " " 24 " "	1.8
5	" " " 48 " "	1.8
		The last test showed a bright yellow colour.

### The Compound Formed.

We have tried how the gelatine combines with the formaldehyde, whether it is a simple addition product or an actual solid combination; whether the group CHO exists, or whether the fixing is merely due to the grouping as in most of the ordinary compounds of formaldehyde.

In order to clear up these points we tested for the aldehyde function in the tanned gelatine by Schiff's reaction, as well as with ammonio-nitrate of silver. We had previously made sure that the gelatine after prolonged washing no longer contained traces of aldehyde that could be detected by these agents. Comparative trials with ordinary gelatine did not give sufficiently marked differences from the formalysed gelatine to enable a definite decision to be formed as to the presence of CHO.

We have also tested, whether the substances allied to formaldehyde, not containing CHO group, such as the bisulphite compound and hexamethylenetetramine, would tan gelatine. The first of

these gave no tanning under any conditions. On the other hand, hexamethylenetetramine in strong solution gave some result after five days when of 50 per cent., and only after seven days when of 25 per cent. Below these strengths there was no tanning.

On account of this slow action and the necessity of strong solutions, it may be assumed that the action is due to traces of formaldehyde in the hexamethylenetetramine; the latter very readily gives the characteristic colour with Schiff's reagent. On the other hand, a very dilute solution of formaline, containing only 0.05 per cent. of formaldehyde hardens the gelatine in about six days.

### Conclusions.

The following conclusions may be drawn from the tests:—

1. Gelatine soaked in formaldehyde solution combines with the latter in varying proportions, according to the conditions. The maximum quantity which it combines with lies between 4 and 4.8 gms. formaldehyde to 100 gms. of dry gelatine, which enables us to consider formalysed gelatine as a definite compound.
2. The rapidity of absorption of the formaldehyde increases with the strength of the solution up to 10 per cent. It does not markedly increase with the temperature.
3. Formaldehyde in gaseous form is absorbed much more slowly than in aqueous solution, but the maximum quantity absorbed in both cases is the same.
4. Hot water slowly decomposes formalysed gelatine, and by repeated treatment the gelatine again becomes completely soluble.
5. Dry heat at 322 deg. Fahr. gradually sets free the formaldehyde from the gelatine; 15 per cent. hydrochloric separates in the cold the gelatine unchanged from the formaldehyde.
6. The formalysed gelatine appears to be rather a definite addition compound than a true compound.

A. AND L. LUMIERE AND A. SEYEWETZ.

## DOUBLE CARBONATES AS DEVELOPERS.

### II.

In my former article I described in some detail my experiences in 1895 with a modified form of pyrogallol developer, in which, in place of the usual simple carbonate solution, a solution of a double carbonate—copper and ammonium—was employed. These experiences, as I pointed out, were sufficiently remarkable, and were such, indeed, as to induce me, after a long interval, in 1905 and the present year, to carry the investigation begun under such favourable auspices a step further.

Accordingly, in pursuance of this object, I proceeded to examine carefully and in detail the various other possible forms of double carbonate capable of efficiently replacing the customary simple carbonate constituent in a pyrogallol combination. The different salts of this class, suitable for use as developers, were enumerated by me in the latter paragraphs of the paper just referred to, wherein I also gave the formulæ for their preparation, and described the method of making up the various stock solutions requisite for photographic purposes.

It is now necessary that I should, in the first place, give some account of the series of experiments which I recently made as to the developing properties of these double carbonates, and that, in the second place, I should supplement this account by indicating and tabulating the chief conclusions—those more especially, of their number possessing a practical importance—that may be drawn from the results of the inquiry.

### Conditions of Tests.

The experiments in question were made in the month of January last. In order to secure uniformity in the conditions of exposure throughout the series, I resorted in every case to contact-printing by ordinary gaslight. The flame employed was that produced by a No. 4 Bray burner. The distance between the printing-frame and the burner during the exposure was one foot. Rapid gelatino-bromide plates were employed, the special brand selected for the purpose of the experiments being the Ilford "Special Rapid." The plates were exposed to the light in the printing-frame under

a glass negative, and the resulting latent positive images were developed in their order in the several specially-prepared developers. The negative selected for use was a very fine one which had been produced by ferrous oxalate development. It exhibited a very wide range of contrast accompanied by great delicacy in the gradation of the half-tones.

In each case, with the single exception of experiment No. 6, an exposure of thirty seconds' duration was given. In the particular case specified, this exposure was accidentally doubled. It is necessary, also, here to explain that the normal exposure of thirty seconds, though somewhat in excess of that actually required under the given conditions, and with the particular brand of plate employed, was selected with the object of permitting the operations of development to be completed within a reasonable time, the slight increase in the exposure enabling this to be done, by serving to accelerate the sluggish action of the experimental carbonate baths.

A thiosulphate solution of the strength of two ounces of sodium thiosulphate to half a pint of water was employed as a fixing bath after the development.

Eight plates were exposed in rotation to light under the negative in the manner above specified, and successively developed in one or other of my specially prepared baths described in my first article. I give below a summary of these experiments.

### Ammonium Carbonate.

First Experiment.—A simple sesquicarbonate bath was employed as developer, the formula of which was as follows:—

Ammonium sesquicarbonate .....	12.5 grains.
Potassium bromide .....	0.5 grain.
Pyrogallol .....	2.25 grains.
Water .....	1 fluid ounce.

The image began to appear after four minutes' immersion in this developer, and rapidly gained in density. When six minutes had elapsed all the details were visible. The development was completed in twelve minutes. The resulting image, after fixing, was

and clear, and from its lack of vigour appeared to be slightly over-developed in addition to being over-exposed. The colour was shade intermediate between olive grey and sepia brown.

#### Magnesium Ammonium Carbonate.

Second Experiment.—The developer selected for the treatment of the second of the exposed plates was the combination pyrogallol and ammonio-magnesium carbonate. The bath was made up for by adding to each ounce of the aqueous acidified solution of double carbonate  $2\frac{1}{2}$  grains of pyrogallol and half a grain of magnesium bromide.

This developer was found to act very slowly, and it was not until nine minutes had elapsed that traces of the image were at length perceptible upon a minute examination of the film by transmitted light. On resuming the developing operations, three minutes' further immersion in the bath rendered all the details visible. The image, however, still very weak, it was found necessary to prolong development for a further period of eight minutes in order to obtain a sufficient degree of density.

The tone of the image after the removal of the plate from the developing bath, was somewhat similar to that obtained in the preceding experiment, but of a distinctly lighter shade. As a picture, the general effect was unsatisfactory through lack of density, this being, doubt, partly attributable to the over-exposure which the plate received, but probably also to the reducing or solvent action exercised by the citric acid in the bath.

#### Uranium Ammonium Carbonate.

Third Experiment.—The developer employed in this experiment was pyrogallol and ammonio-uranium carbonate. To each ounce of the aqueous stock solution of the double carbonate there was, as before, added  $2\frac{1}{2}$  grains of pyro, and half a grain of potassium bromide.

In development, no signs of an image were to be detected until the expiry of eight minutes, when the faint outlines of the picture were just barely perceptible by transmitted light. The subsequent growth of the image proceeded with extreme slowness, and in account of the general fog which unfortunately ensued in the course of the next few minutes, the stage in the operations at which the details became fully visible could not accurately be determined.

The fixed and finished positive was of considerable photographic quality. The colour of the image was a rich deep red, somewhat resembling that obtained with the ammonio-cupric carbonate developer. In density and in range of tone the result also left little to be desired. The only noticeable defect was a certain lack of clarity, which was apparent in the high lights of the picture.

#### Cobalt Ammonium Carbonate.

Fourth Experiment.—The bath employed in this case was the cobalt-ammonium carbonate developer. To each ounce of the specially-prepared stock solution of the double carbonate  $2\frac{1}{2}$  grains of pyrogallol were added. The usual bromide restrainer was, however, omitted.

The image made its appearance after an immersion of one minute, when three minutes had elapsed, all the details of the picture were visible. On continuing the process of development a rapid increase in density was perceptible. The duration of development was nine minutes.

The general result was unsatisfactory, notwithstanding that the colour of the picture after fixing—a dark brown—was both common and agreeable. The density obtained was considerable, the image was lacking both in clearness and in range of tone, the minute stains and irregular markings were visible on a close inspection of the film by transmitted light. These defects were, doubt, attributable to the omission of the bromide restrainer, but also, it is to be presumed, to the turbidity of the cobalt-ammonium bath in the presence of pyrogallol.

#### Copper Ammonium Carbonate.

Fifth Experiment.—In order to test the keeping qualities of the copper-ammonium carbonate developer, the remainder of the stock solution prepared in 1895, after the manner described in my former article was selected to develop the fifth plate of the present series. The developer was made up to the usual strength of  $2\frac{1}{2}$  grains of pyrogallol per fluid ounce, to which was added half a grain of potassium bromide as a restrainer.

After a treatment of one minute's duration in this bath, very faint traces of an image were visible by reflected light, and after three minutes' development these outlines could be plainly discerned when the plate was removed from the dish and examined by transmitted light. Fogging, however, speedily ensued when the development was resumed, and when three minutes more had expired the growth of the details could no longer be watched, and in the course of a little the film became almost opaque. The development was proceeded with until one hour had elapsed.

The finished picture, though evidently considerably over-exposed, was fairly satisfactory, and was found to possess a medium degree of density and gradation of tone. The colour was a fine deep orange, lacking, it is true, the purity and richness of the hue obtained in 1895 with the freshly-prepared developer, but still very characteristic and striking. The lack of vigour observable in the image was in part probably due to the carbonate solution having deteriorated and become weaker through age.

#### Zinc Ammonium Carbonate.

Sixth Experiment.—The plate used in this experiment received the exceptional exposure of sixty seconds. The development was effected with the zinc-ammonium carbonate bath. To each ounce of the stock solution of the double salt the usual quantities by weight of pyrogallol and bromide were added.

Traces of an image were faintly visible by transmitted light when the plate had been immersed in the developer for two minutes; and in the course of an additional thirty seconds' development these could be discerned from the surface side of the film. The subsequent growth of detail was somewhat rapid, and at the end of four minutes' treatment the full outlines of the picture were clearly perceptible. To gain a sufficient degree of density, however, it was thought advisable to continue the development for the space of sixteen minutes longer.

The positive produced by these operations was the least satisfactory of the series, the density being excessive and the high lights lacking in clearness. The half-tones, also, were deficient in vigour. The colour of the image was a very deep chocolate brown. The fact deserves mention that, when fixing the plate, it was discovered that little or no fog had been produced in the course of the developing operations, a circumstance which, of course, permitted of the process of dissolving out the unaltered silver bromide being carried out more speedily than usual.

#### Restrained Cobalt Formula.

Seventh Experiment.—The seventh of the exposed plates was treated with the cobalt-ammonium carbonate developer, as in the fourth experiment of the series, a restrainer being, however, now added for the purpose of moderating the chemical activity of the bath. In making up the developer for use the customary quantities of pyrogallol and potassium bromide were added to the stock carbonate solution.

At the expiry of two minutes and a half after the immersion of the plate, the image appeared faintly. The growth of density thereafter was comparatively rapid, and all the details were visible at the end of five minutes. The plate received a development of a quarter of an hour's duration.

The resulting image was, beyond question, the finest of the series. The gradation of tone which the plate exhibited was very pleasing to the eye, as was also the purity of the high lights; while the density, though more than sufficient to produce a bright and vigorous picture, was at the same time quite free, even in the deepest shadows, from any suspicion of hardness or opacity. The colour produced was a rich and beautiful yellow-brown, specially remarkable for the warmth and brilliancy of its middle tones.

#### Nickel-Ammonium Carbonate.

Eighth Experiment.—In this, the concluding experiment of the series, the nickel-ammonium carbonate developer was employed. The developing bath was made up for use by adding to the specially-prepared carbonate solution the usual quantities of pyrogallol and potassium bromide.

As a developer, this solution was found to act more energetically than any of the baths employed in conjunction with a restrainer as above described. The first indications of the image were perceptible

after only one minute's immersion of the exposed plate in the bath. When seven and a half minutes had elapsed, the picture was rendered visible in all its details. The duration of the development was twenty-four minutes.

The image, after fixing, was weak and wanting in clearness, and exhibited a very limited range of tone. The colour obtained was a sepia brown of no special beauty. As I mentioned in the former article, it was found necessary, in making up the nickel-ammonium carbonate solution, to add a considerable percentage of sodium sulphite, and the hue of the image obtained in the experiment, probably owing to the presence of this salt, greatly resembled that produced by the action of the pyro-sulphite and ammonia developer.

With the object of showing at a glance the character and respective numerical values of the results of the above series of experiments, and of so facilitating the comparison of the merits and defects of the developers themselves, I have prepared the table here given, which has been drawn up on somewhat similar lines to that appended to my paper on "Development with the Alkaline Carbonates," published in this journal on September 28, 1894.

No. of Experiment.	Exposure in Seconds.	Amm. Carb. and Carbonate or Oxide of	First Appearance of Image.	Details wholly Visible.	Duration of the Development.	Order of Merit.	Density of Image.	Range of Tone.	Clearness.	Colour of Image.
			M.	M.	M.	(1 > 8).	(1 < 8).	(1 > 3).	(1 > 8).	
1	30	—	4	6	12	2	3	1	2	Olive
2	30	Magnesium	7	10	18	4	1	2	1	Light
3	30	Uranium ...	8	doubtful	70	3	7	2	5	Deep r
*4	30	Cobalt ...	1	3	9	7	6	3	7	Dark
5	30	Copper ...	1 to 3	doubtful	60	5	4	3	4	Deep o
6	60	Zinc ...	2 to 2½	4	20	8	8	2	8	Intense
7	30	Cobalt ...	2½	5	15	1	5	1	3	Yellow
8	30	Nickel ...	1	7½	24	6	2	3	6	Brown

In the column headed "Order of Merit," the numerals represent a diminishing series, of which 1, the first member, represents the finest image, and 8, the last, the least meritorious of the number.

Under the heading "Density," again, the maximum density obtained is shown as 8, and the minimum as 1. In regard to the column headed "Range of Tone," in which the numerals 1 to 3 are seen to occur, the first represents the maximum, the second a medium degree, and the third, a minimum, of tone gradation. In the tenth column, headed "Clearness," the numerals 1 to 8 are again employed, unity, as before, representing the maximum and 8 the minimum degree of this quality, as obtained in the experimental series under review. Experiment No. 4, in which, as already mentioned, the usual bromide restrainer was omitted, is marked in the first column with an asterisk.

On a comparison of the figures in the fifth, sixth, and seventh columns of this table, showing the several stages in the process of development, it will be noticed that certain carbonates—viz., those of cobalt, zinc, copper, and, more doubtfully, nickel—appear to act as accelerators when employed in conjunction with the pyro and ammonium carbonate bath. In the case of the cobalt and zinc baths, as the table shows, this accelerating action manifested itself very prominently. There is some little doubt as to whether the nickel-ammonium carbonate developer, which also was found to act with considerable energy, should be classified with those just mentioned, as being, *per se*, an active carbonate bath, seeing that the sulphite

which was added to the stock solution may possibly have contributed in some degree to accelerate the developing properties of the carbonates present. The copper developer should probably be viewed in the light of the figures given in the fourth column of the table, classified among the baths of the active type.

The least energetic of the baths experimented with was that in which was employed to develop the third plate of the series. In this the uranium salt seems to have exercised a restraining influence.

Turning next to the eighth column of the table, and arranging the baths in their order according to the degree of density obtained in each case, it will be seen that the series, beginning with maximum density and ending with the minimum, runs as follows: Zinc, uranium, cobalt, copper, nickel, magnesium.

If we adopt a similar system of arrangement with regard to property "Range of Tone," we find that the baths must, in that order, be grouped thus:—

Cobalt [uranium, zinc, magnesium], [copper, nickel], in which series those members enclosed within brackets represent baths which were found to possess nearly similar properties.

respective of their capacity to produce the quality in question.

Again, if we arrange the figures contained in the tenth column, headed "Clearness," proceeding as before, from maximum to minimum, it will be found that the baths must be grouped correspondingly in the order given below:—

Magnesium, cobalt, copper, uranium, nickel, zinc.

In concluding this summary, I shall not attempt any classification on similar lines to the above of the results of experiment, but, as to the colour of the image, this being a factor of too variable an individual character to be capable of being expressed in numerical terms. It may suffice to say that the finest results, as regards particular quality, were those obtained with the uranium, cobalt and cobalt baths, the colours given by these being very beautiful and characteristic. Of the shades of colour produced, the non-actinic was that due to the action of the uranium bath, the least non-actinic that produced by the employment of the ammonium developer.

In conclusion, I may state that out of the six specially-prepared carbonate baths which I have experimented with, four—namely, cobalt-ammonium, the copper-ammonium, the uranium-ammonium, and the zinc-ammonium, seem to possess properties which render them suitable for employment in practical photography, and to which, in particular I would therefore direct the attention of such as are interested in working out new problems in the important field of development.

MATTHEW WILLIAMS.

**COMPARATIVE Costs of Lighting.**—The following figures are given by the "Chemist and Druggist," as those of Dr. George Lockemann. They show the number of German standard candles, i.e., candle power, obtainable in an hour from one shillingworth of the respective illuminant, which should be of interest. Cost of maintenance is taken into account and average values attached to the materials or electric current as the case may be. (A kilowatt-hour costs 40pf. = nearly 5d. in Berlin, and 70pf. = nearly 8½d. in Leipsic.) Wax candle 29, stearine candle 79, composition candle (2 parts paraffin, 1 part stearine) 103, paraffin candle 117, colza oil in lamp with ordinary wick 131, colza oil in "moderator" lamp 380, coal gas (ordinary slit burner)

418, coal gas (Argand burner) 586, Edison electric lamp 662, Edison electric lamp 1,064, spirit glow lamp 1,136, petroleum Argand lamp 1,205, osmium electric lamp 1,290, tantalum electric lamp 1,299, gas regenerative burner 1,299, arc electric lamp 1,818, coal gas (Lucas high draught burner) 2,632, coal gas (Lucas high draught burner) 3,704, coal gas ("Millennium" pressure burner) 5,000, Bremer electric arc lamp 8,547 candles.

Messrs. W. L. PARKINSON, LTD., announce that they have removed from 62, Dale Street, Liverpool, to more commodious premises, centrally situated at 5, Commutation Row, opposite Wellington Monument.

## GUM PRINTS IN COLOURS FROM A SINGLE NEGATIVE.

In the current issue of "Camera Craft" is the description which we of Indian photographs of Mr. E. S. Curtis, upon whose specialisation is stated by its author, Mr. A. F. Muhr, to be original with him, printing.—Eds. B.J.P.

quote below of the method employed in printing the large series photographic career we have commented more than once. The method, although it will be seen to be along the general lines of multiple gum

Several years ago, when I had made my first gum print, a sketchy head in red chalk, it at once suggested the possibility of attaining colour effects which might prove a revelation, though not simple enough to become commercially available. A long time elapsed before I could put my theories into practice, but I had so thoroughly thought out the details that my first attempt gave ample proof of the value of the suggestion, the correctness of my theory.

When Mr. E. S. Curtis first displayed these pictures in Washington, D. C., and New York City, they excited great interest and much comment. What is, perhaps, most gratifying and speaks more favourably, they were bought at high prices by people who are known to be among the leading connoisseurs and collectors, upon the suggestion of some of the greatest art critics in the East. However, opinion was divided, for the artists on viewing them and detecting the product of the negative, said: "It is not art." The photographers, seeing the handiwork of the artist peeping through the print, said: "It is not photography." These pictures were thus relegated to a nondescript position between the two. Very often this sign, \$, becomes the true standard of value, and causes others to inject the mercenary question: "What is there in it?" To these we say that the prices obtained were both encouraging and gratifying.

### Wanted, Draughtsmanship and Colour Sense.

In producing these prints, the most important requisite, in my estimation, slight though it may be, is a knowledge of painting. I find that my early experience in sketching from nature, an accomplishment which has been, unfortunately, neglected for many years, is of inestimable value to me. In applying the sensitised pigments I find myself taking up first one, then the other colour, as an artist takes them from his palette. Some knowledge of this kind will also enable me to form a clearer idea of the tone quality desired to be produced; one that will harmonise with the subject to be treated. It is in the production of tone pictures, the *Stimmungs-Bilder* of the Germans, the symphonies and nocturnes of a Whistler, that this method lends itself admirably and gives the most pleasing and satisfactory results. To obtain these, a simple palette, that is, one of but a few colours is necessary.

### The Coating Formula.

So much has been written on the rudiments and technique of gum-bichromate printing of late that one is inclined to say that any old formula will answer admirably with which to form an acquaintance with this simple but interesting process. My stock solutions are bichromate of potassium, one ounce in ten ounces of water; gum arabic in large, clear tears, two ounces in ten ounces of water. Finely ground colours, to be obtained at any paint shop, complete the list. I have used tube water colours, but find that the dry colours give a more satisfactory result. The beginner should acquaint himself thoroughly with the relation which colour and gum hold to his particular quality of negative, bearing in mind that an excess of either produces contrast, and, on the other hand, a minimum quantity will give more detail, better half-tones, and better gradations. Furthermore, the colour itself is an important factor. Blue prints more rapidly than black; brown, red, and yellow following in the order named. It is self-evident that the more pigment added to the emulsion the longer it will take the light to penetrate, hence care should be taken to add a sufficient excess of the quick printing pigment to compensate for those of a lower scale. A great deal of patience and perseverance are necessary, and one must not be discouraged at failure in the beginning. Remember that one success is worth a barrelful of failures.

### Coating the Paper.

Pre-supposing a knowledge of the values of the simple colours—blue, red, and yellow—and the results of their being superimposed, we may coat the paper, proceeding somewhat in the manner of a rough sketch by "blocking in" the colours in bold masses, conforming the outlines to the image of the negative. Before the gum sets

the next colour must go where it belongs, and so on, until the paper is covered. Use as broad a brush, or brushes, as may be consistent with the smaller masses of the subject. The detail, of course, is obtained from the negative in printing. The paper is then hung up to dry, which will take but a short time, an hour being ample. It may then be printed.

The colours are stirred carefully in equal parts of the gum and bichromate solutions, the quantity depending on the effect desired to be produced. Variations in the quantity of pigment used and the time of exposure change the effect of the print entirely. The paper is pinned to a board, and should be coated or covered as rapidly as possible.

### Development.

I have always used the paper without preparation, preferring the heavy, rough Whatman paper for our work. The shrinkage, especially in large work, is not detrimental. On the contrary, the slight fuzziness caused by the imperfect registration, blurs the outline and adds to the artistic quality. While on this subject I will speak of register marks. I use both the corner mark and lines through the axis of the paper in both directions. These lines enable one to strike the comparative centre should the paper shrink more than usual.

As there is no visible image while printing, except in some of the thinner coatings of light colours, a photometer should be used. To make a test, coat a strip of paper with the emulsion and expose under the negative to be printed, at the same time exposing a strip of printing-out paper in the photometer, and so determining the correct exposure. When the print has been made, development may be proceeded with at once. In fact, it is more satisfactory to develop soon after printing, as chemical action continues in the print after its removal from the frame, and this would easily lead to wrong conclusions as to proper exposure. The development is the most interesting part of the process. A great deal depends on the preceding steps, but in development one comes to the making of the picture, and the greatest care and patience must be exercised. Slide the print face downward into a tray of water, and after a few minutes turn it over slowly and carefully. Do nothing violently, or everything may be spoiled. Let nothing touch the face of the print, and do not let water spatter on it. In five or ten minutes the high lights should be visible; in a half-hour the middle tones should be out, and in an hour the print ought to be fully developed.

In the beginning of development the water should be changed two or three times, as the bichromate is discharged from the print. This is best accomplished by removing the print from one tray to another. Be in no hurry to use the brush, and do not become impatient. I have hung over a print for two hours, and the result amply repaid me for the time and trouble. When the print shows the effect desired you may touch it sparingly with a brush. Have you ever watched the affectionate care with which an artist puts the finishing touches on his painting? Adding a high light here and a dark touch there by way of accentuation is all he does. That is all that is required in our work, a touch here and there. After prolonged development a 2 per cent. alum bath is not required, as a soluble bichromate has all been removed. Now hang up to dry.

### The Two After-Printing.

The next coating is a combining or harmonising coat. This is rather poor in colour, and applied quite thin with a broad brush all over the paper. Drop black or lamp black, with a touch of magenta or prussian blue, or burnt umber, according to the effect desired, is added sparingly to the gum-bichromate. When dry, print and develop in the usual manner, but you may be more bold in the use of the brush. This should tone down all harsh lines left from the application of the colours in the first coating. The third and ultimate printing should be made with heavy emulsions, both as to colour and gum, as they are to accentuate the heaviest shadows. The

exposure should be rather short so that the deposit may be washed from all parts of the print, except the shadows.

This is the method which I have worked out independently and successfully used. In the main, it corresponds with other methods; in the manipulation it is as different as the results are different.

## NOTES ON SULPHIDE TONING OF BROMIDES.

A Paper in "The Australasian Photo-Review."

WHEN I first started using this sepia toning process, I noticed that the tones were not uniform, even though the same paper, developer, and bleaching bath were used. Sometimes I obtained a cold sepia, sometimes a warm sepia, and at other times a disagreeable yellow-ochre.

The cold sepia is very suitable for some subjects, and the warm sepia for others, especially when a cream-tinted bromide paper is used; so, if possible, I determined to find out the exact conditions which affect the tone of the toned print. The different factors are:—

1. Developer.
2. Degree of development.
3. Presence of potassium bromide in the developer.
4. Bleaching bath.
5. Paper.

1. Developer.—This has been discussed by Mr. Gates in a previous paper\* in the "A.P.-R." I find, however, that it is possible to get any of the tones with any of the developers, e.g., I can get a cold sepia with hydroquinone, although it is prone to give warm tones; generally low factor developers tend to warm tones.

2. The degree of development also affects the tone, in that short development gives warm tones, prolonged development cold tones; but it is not necessary to carry development to the ultimate limit of reduction for cold tones.

3. The presence of potassium bromide tends to produce warm tones in the toned print unless development is protracted, i.e., if we wish to obtain a cold sepia, development must be carried on much longer after the appearance of the image than if it were absent; it also increases the contrast of the print, for it will be noticed that when it is present the print has greater contrast, and presently development slows down, until a temporary limit is reached. If now development is carried on further the print gets softer, because the high lights fill in, and ultimately the contrast is the same as if there had been no bromide present. Now, we can get a cold sepia before this temporary limit, that is, it is not necessary to sacrifice contrast to get a cold sepia tone when using bromide to give contrast.

4. The bleaching bath affects it slightly, but I do not find much difference in the result. It is better to eliminate any varying factor, i.e., adhere to our bleaching bath.

I find that rapid papers, such as Kodak or Wellington, give colder tones than the slower brands like Pearl; but by prolonging development I can easily get cold tones with slow bromide paper. With gaslight papers it is difficult to get cold tones, and, with some, impossible.

In practice, however, it is advisable to simplify as far as possible, and if the following plan is followed the resulting colour will be automatic.

In this method I made an exposure through a negative, giving the correct exposure, and then cut the paper into twelve strips, numbering them in order, and then placed them in order on a glass plate, holding them in position by a small rubber band at each end.

I then poured on the following developer, and five seconds after the image appeared (ten seconds) I removed the first, and immediately put it into an acid fixing bath, and five seconds after this I removed the second, and the rest in order, allowing five seconds' interval each. Developer:—

Amidol .....	2 grs.
Soda sulphite .....	22 grs.
Water .....	1 oz.

\* February

It is a process of great promise, wonderful possibilities and extreme fascination. It furnishes a medium which gratefully lends itself to the worker striving for artistic effects, giving such a temperament unlimited latitude, besides marking the result with the stamp of his own individuality.

I then repeated the experiment with bromide in the developer, thus:—

### Tabloid formula.

Amidol .....	2 grs.
Soda sulphite .....	22 grs.
Potassium bromide .....	1 gr.
Water .....	1 oz.

Allowing ten seconds' interval between each. Then a third time with:—

Amidol .....	4 grs.
Soda sulphite .....	44 grs.
Potassium bromide .....	4 grs.
Water .....	1 oz.

Allowing ten seconds' interval after fixing, they were washed, and then bleached in:—

Potassium ferricyanide .....	20 grs.
Potassium bromide .....	20 grs.
Water .....	10 ozs.

Rinsed a minute, and then darkened thoroughly in a 1 per cent. solution of soda sulphide.

(N.B.—The "tabloid" formula gives identical results.)

In Experiment 1.—Cold sepia was obtained fairly early.

In Experiment 2.—The first tones were a disagreeable yellow-ochre, then through warm sepia to cold sepia. The last tone was obtained just before the temporary limit.

In Experiment 3.—The tones were similar to Experiment 2, only they were warmer throughout.

Also, Series 2 had greater contrast than Series 1, and Series 3 had greater contrast than Series 2.

No. 1 developer is suitable for negatives suited to platinotype or carbon.

No. 2 developer is suitable for negatives suited for P.O.P.

No. 3 developer is suitable for negatives suited for soft gaslight.

Now, suppose my negative is of such contrast as demands No. 2 formula and I want a certain colour. I find this colour on the chart and note the time opposite; say, 1 minute 30 seconds; I then make three or four successive exposures on a trial slip, and develop this trial for this time (1 minute 30 seconds) and fix it. In a bright light I determine from the slip the correct exposure for such development. I now give this exposure to the whole piece, and develop it for this time, and then I am perfectly sure that it will tone to exactly the desired result.

If the result is deficient in contrast, I use the next formula containing more bromide. You may either adopt these formulae or work out similar charts for the particular developer you employ, e.g., M.Q. or Nodinal are excellent developers.

### SUNDRY NOTES.

After the sulphide bath you will find the gelatine very soft and shiny, and very liable to abrasion. If you immerse it in a weak solution of alum it instantaneously toughens like leather.

If by any chance the washing apparatus is rusty, or by any means you get iron into the print, you may get a blue stain in the paper from the ferricyanide. This may be removed after the sulphide bath by immersing the print in a weak solution of hydrochloric acid.

NORMAN C. DECK.

## THE OPACITY COMPARATOR.

the current number of the "Revue des Sciences Photographiques," Monpillard describes a new instrument for the measurement of opacities, which is constructed by M. Nacet, and enabling them to read direct.

The source of light is an incandescent gas burner, surrounded by metal chimney B, pierced by a hole through which proceeds a beam of light, which is rendered slightly divergent by a strong plano-convex lens L, and is directed to the two mirrors M of the comparator, Fig. 1.

Between the instrument and the lens is placed a movable vertical screen E, which allows that portion of the light which falls on the mirrors to pass, but protects the observer entirely from the light.

Fig. 1.

The beam of light projected by the lens is reflected vertically by the two mirrors MM, after passing through the two apertures OO, the plate, on which are placed the prisms; each beam is reflected horizontally towards the other by a total reflecting prism *a*, and falling on the two faces of the rectangular prism *b*, are reflected by the two faces to the eyepiece. The upper part of this eyepiece carries a pinhole aperture, in other words, it is diaphragmed so that the observer is forced to see the apex of the prism, and any parallax avoided, Fig. 2.

The mirrors having been properly adjusted, a field is seen, in the

Fig. 2.

eyepiece, divided into two equal parts by the apex of the prism, each portion being illuminated by one of the mirrors, Fig. 3.

The stand on which are mounted the prisms and the eyepiece carries two sliding tubes, exactly over the axes of the apertures in the plate, so as to prevent the access of stray light, save that which passes through the plate.

Each aperture in the stage is 10 millimetres in diameter, but it is arranged that the field may be reduced to 5 mm., or a rectangular field of 10 x 3 mm. may be used; this last makes it very easy to examine the bands in a spectrogram, Fig. 4.

"TABLOID" Metol Quinol Prize Competition. The latest date upon which entries for this competition can be received is November 25. Competitors who have not secured entry forms should obtain them at once from their dealers or direct from Burroughs, Wellcome and Co., London, E.C.

Finally, below the stage is placed a movable piece, Fig 5, which, turning on its axis, enables ones to simultaneously place over each aperture a piece of smoked glass of a medium tint. The interposition of this screen reduces the intensity of the illumination and facilitates, to a great extent, the examination of very slight densities.

To use the instrument, it is only necessary to orientate the mirrors so that the two halves of the field are equally illuminated, an operation which is extremely easy. The test print is placed over one of the apertures of the stage, the eye placed at the ocular, and then the other plate passed over the other aperture till the two fields are equally illuminated.

If the intensity is very feeble then there is the advantage of being able to place the smoked glasses over the apertures.

The eye receiving no impression save that through the eyepiece, the observer is under the most favourable conditions to rapidly and accurately compare the intensities.

If how we wish to determine the value of these intensities, all that is necessary is to transform our comparator into an opacity meter. To do this, one of the tubes, that below the prisms, is movable, and can be removed from its grooves and is replaced by the measuring apparatus P, Fig. 1. This is composed of two Nicol prisms,  $p^1$   $p^2$ , Fig. 2, of which one is fixed and the other can revolve on its axis. This angular displacement, which is 90 degrees, can be measured by an index, which is displaced on the arc of a circle divided into degrees.

In the other tube, that of the opacity meter, it is necessary to introduce another Nicol  $p^3$ , which acts as a compensator, and annuls

Fig. 3.

Fig. 4.

Fig. 5.

the elliptical polarisation produced by the reflection of the light rays from the surfaces of the prisms.

In order to measure with this, it is only necessary to place underneath the tube carrying the compensator Nicol, the plate to be measured, and then to move the handle that rotates the Nicol till the two fields are equally illuminated.

The index at which this stops is the angle of rotation of the Nicol; it is then very easy, by a simple calculation, to determine the intensity of the beam of light corresponding to this angle; this intensity being exactly equal to that of the same beam of light after passing through the plate that had to be measured. We are then in possession of all the data necessary to determine, by means of a table prepared for this purpose, the coefficient of the absorption resulting from the deposit of silver in the plate, its opacity, etc.

The same arrangement of this instrument presents this advantage: that it permits one to obtain at once the absolute value of the density. Deduction is made of the quantity of light reflected by the surface of the support, glass or celluloid, of the absorption produced by the vehicle itself, gelatine, or collodion, and finally of the development fog.

In conclusion, this small apparatus, which is very easy to use, gives, with certainty and rapidity, the data, more than sufficient from the point of view of accuracy, for the measurement of the density of photographic plates.

ROYAL Photographic Society.—In addition to the exhibits to be shown at the opening of the Royal Photographic Society's Rooms next Tuesday, which were announced in our last issue, demonstrations of three-colour work will be given by the Rotary Photographic Company.

## MR. J. T. SANDELL.—AN APPEAL.

Since the publication of last week's list we have received the following donations to the above fund:—

E. J. Wall ... ..	£	s.	d.
E. W. Foxlee ... ..	0	10	6
H. J. Burton ... ..	0	5	0
H. J. Burton ... ..	0	10	6

The following donations have also been subscribed to the fund through Messrs. T. K. Grant and J. B. B. Wellington:—

E. Sanger Shepherd ... ..	1	1	0
Sir David L. Salomon ... ..	2	2	0
Bromley Camera Club (per T. D. Grady) ... ..	0	10	6
G. W. Watson ... ..	1	1	0
Andrew Pringle ... ..	1	0	0
G. T. Mansfield ... ..	1	0	0
Darlington Camera Club ... ..	0	4	0
F. W. Hindley ... ..	1	1	0
A. Seaman ... ..	0	5	0
F. T. Bernau ... ..	0	5	0
R. Kirkby ... ..	0	1	0
Taylor, Taylor, and Hosson ... ..	1	1	0

Total ... .. 109 18 0

## Exhibitions.

## WEST OF ENGLAND EXHIBITION.—PHOTOGRAPHIC SECTION.

THE photographic section of the exhibition was opened last week. The photographs are not housed well, the room being low and depressing, but the committee have done everything they could to make the surroundings effective. The exhibits do not reach quite as many as before, and there is nothing striking to be noted, though there is much that is enjoyable, and should be educational to the photographers of the west.

Great praise is due to Mr. S. C. Croft for the excellent way in which the exhibits have been hung.

The Champion Class A.—An excellent collection of varied styles and subjects, most of which are agreeable and pictorial. The first place, gold medal, goes to "Twilight and evening bell, and after that—the dark," O. C. Wilmot, a delicate print of much excellence and evincing considerable artistic perception; but we cannot think it is better than "October" (also an evening and twilight subject), by Fred. Judge, more pictorial in selection and technically very good. This is awarded a diploma. The second place, silver medal, is secured by "Going to be Shaved," by S. R. Stevenson, and represents a procession of monks, apparently in Rome, or a city of similar architectural character, full of life, with a happy combination of adjuncts and of good technique. Third place, bronze medal, goes to "Tugging Home," W. Clayden. This print has done a long and weary round of exhibitions, and though it has very fine pictorial quality, yet its producer might now be well satisfied and do something to win more deserved laurels. Diplomas are awarded to "Binding the Wheel," A. E. Coleman, a scene in a wheelwright's shop; "October," already mentioned; and "Ain't It Nice?" E. V. Hearn, a nude very young lady in a bath, natural, and very pleasing.

In the other classes the awards are (except in Class S.): 1st silver, 2nd bronze, 3rd diploma. There are also prizes offered by the Mayoress of Plymouth, a gold medal by the "Western Morning News" Company, a prize by Moon and Sons, to the lady whose pictures obtain the highest number of points, a "Photogram" plaque, a gold medal, presented by the "Western Daily Mercury," to the winner in Class H., prizes by Foster and Sons, a prize by George Newnes, Ltd., and a prize by the secretary.

NEW Studio at Bognor.—Mr. W. R. Goodyer has opened, at 35, High Street, Bognor, as the "Goodyer Studio."

IPSWICH Camera Club.—Mr. S. B. Bond has resigned the post of hon. secretary, and Mr. T. A. F. Crisp, 14, Redan Street, Ipswich, has been appointed (pro tem.) in his place.

## Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

The following applications for Patents have been received October 15 to October 20:—

CAMERAS.—No. 22,868. Improvements in or relating to photographic cameras. Julian D'Arcy Eveyard, Reedhamptoncoote, Putney, Surrey.

DISHES.—No. 22,907. Improvements in dishes for photographic poses. Johann Nepomuk Schram, 31, Bedford Street, Strand, London, W.C.

APPARATUS.—No. 22,994. Improvements in photographic apparatus. Robert Barr, 9, Warwick Court, Gray's Inn, London, W.C.

TELEMETERS.—No. 23,052. Instrument for measuring distances of short range, particularly applicable to photographers' use. George Logan Clarke, 37, West Nile Street, Glasgow.

CAMERA STANDS.—No. 23,097. Improvements in stands for photographic cameras. Frederick Hook and the Service Company, London, Ltd., 23, Southampton Buildings.

## COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

SHUTTERS.—No. 23,488. 1905. The claim is for a spring-operated friction arm in combination with a temporary detent for controlling the duration of the exposure, the rapid closing opening of the lens aperture being effected by a suitable spring as shown at *a*<sup>1</sup> Fig. 1, and at *a*<sup>2</sup> Fig. 2, irrespective of the interval of time for which the shutter may be adjusted.

Fig. 1.

The swinging of the shutter plate and of the friction arm are simultaneous, by virtue of the pin fixed to the safety cover pressing on the trip plate of the arm, and the parts are adjusted so that the arm and the quadrant plate are released at the same moment; the latter, instead of merely returning to its original position, is held at the exposing position by the spring detent, and remains thus until the friction arm returns and disengages the detent, when the quadrant plate is free to complete its return movement.

It follows that the duration of the exposure depends on the rate of the return movement of the friction arm, and at every speed the shutter may be set, the lens aperture is open for practically the whole time. For the most rapid exposures, the clamping screw is loosened, and the arm, in its return, throws the spring detent out of the path of the quadrant plate, allowing the latter to return to its original position without obstruction. For time exposures, a stop is turned in the path of the friction arm, and keeps it out of gear with the spring detent, the closing of the shutter taking place on the return of the safety cover as usual.

*a* Fig. 1 is the safety cover pivoted at *b*, and provided with

stud *c*, which engages in the slot *d* of the releasing lever *d*<sup>1</sup>. It is also furnished with a turned up lip *e* for engaging with the spring catch *f* of the shutter plate *g*.

The shutter plate *g* is also pivoted at *b*, and provided with an exposing aperture *h*, a closing spring *h*<sup>1</sup>, a stud *h*<sup>2</sup>, for throwing the friction arm back prior to exposure, and a stop *i*, which engages with the spring-operated pivoted catch *k*, as shown in the drawing.

The friction arm *l* is pivoted at *l*<sup>1</sup>, and is held under varying degrees of compression between the flat plate *m* and the spring plate *m*<sup>1</sup>, the spring *n* tending to carry it towards the pin *o* on the pivoted catch *k*.

In Fig. 1, the shutter plate is shown in the exposing position. It remains thus until the friction arm *l* returns, under the influence of the spring *n*, and strikes the pin *o* on the catch *k*, and disengages the latter from the stop *i* of shutter plate, which then rapidly flies to the stop *p* by virtue of the closing spring *h*<sup>1</sup>. The lens aperture now being closed, pressure is removed from the release knob *d*<sup>2</sup>, and the return spring *d*<sup>3</sup> operating the release lever *d*<sup>1</sup> turns the safety cover until the lip *e* engages the spring catch *f* on shutter plate, in which position the safety cover closes the exposure aperture, and prepares the shutter for the next exposure.

Fig. 2.

The act of depressing the release knob rotates the safety cover and the shutter plate, until the former meets the stop *g*, fixed at a suitable position in shutter board. This stop by contact with the spring catch *f* releases the shutter plate, which then flies to the open position as shown in diagram.

During the turning of the shutter plate, the stud *h*<sup>2</sup> has thrown the friction arm *l* away from the pin *o* on pivoted catch, allowing the latter to come into action as a temporary detent to hold the shutter plate at the exposing position until released by the return of the friction arm described.

The regulating knob, not shown, is threaded on the pin *l*<sup>1</sup>, which projects through the camera front, a pointer and dial being adopted to indicate the rate of exposure at which the parts are set. In rapid exposures the friction arm returns simultaneously with the release of the shutter plate, and the temporary catch is inoperative.

In Fig. 2 the system is shown combined with the sliding plate type of shutter, *r* being the releasing lever, which, when depressed, carries the safety cover *s* and the shutter plate *s*<sup>1</sup> across the lens aperture *t*. The shutter plate, being provided with a detent spring *u*, which engages over a lip *u*<sup>1</sup> of safety cover, the stop *u*<sup>2</sup> throwing the detent spring out of gear when the safety cover completes its movement. This condition is shown in diagram. The shutter, having flown to the exposing position by the action of the spring *r*<sup>1</sup>, is held thus by the spring catch *v*, until the latter is thrown out of gear with the stud *v*<sup>1</sup> on the shutter plate by the return of the friction arm *l*, precisely as in the case formerly described. James Albert Watts, 158, West Green Road, South Tottenham; and Houghtons, Ltd., 88 and 89, High Holborn, London, W.C.

The following Patent is open to public inspection before acceptance under the Patents Act, 1901:—

CATATYPE PRINTING.—No. 21,584. Process for converting silver pictures into pictures in higher oxides of manganese and for toning silver pictures and baths therefor. Neue Photographische Gesellschaft.

## New Books.

"Photochemie und Beschreibung der Photographische Chemikalien."

By Ernst König. Berlin: Gustav Schmidt, M 11.

Dr. König has undertaken the laborious task of revising the text of this work as the late Dr. H. W. Vogel left it in 1880. In performing this duty—for the re-edition of Dr. Vogel's lengthy volumes may be so described—he has adhered to the salient feature of the original work in that he has not divorced the scientific facts of photography from their applications. Hence it is that the present volume is a good deal more than the dry bones of theories. It contains a goodly proportion of what is often referred to as "practical" information a combination, which is desirable, as it promotes the study of theory by the "practical" people and of practice by the theorists. This dual study of the two aspects of the subject is more necessary in photography than in any other branch of applied science.

The contents may be divided into two parts—viz., that dealing with the action of light and that treating of the properties of chemical substances chiefly in their applications to photographic processes. Both parts are treated very fully, and as, indeed, should be the case in the 380 pages. The sections on dyes for orthochromatic sensitising, and on the chemistry of the colloids, will probably be welcomed as warmly as any, since chemical progress has brought more facts to light in these departments than in the older inorganic chemistry. A few supplements are included, among which is a set of bromide prints from three-colour negatives.

"How to Buy a Business." By A. W. Bromley. (London: T. Fisher Unwin.) 2s. 6d.

A paragraph in the first chapter of this book will show that the author dispenses advice which may be offered for the serious consideration of those proposing to enter the photographic "profession." Itemising the factors requisite in a trader, he says: "Business capacity undoubtedly comes first. It is more important (for his own success, at any rate) for a shopkeeper to be a good business man than for him to know the practical details of his own business. A man may know all that is to be known about the business he is engaged in, but without business ability he will rarely make a success. On the other hand, there are many brilliantly successful men who are disgracefully ignorant on technical matters connected with their business." That this is true, even in a technical business such as photography, is most certain, and is accountable for many of the failures which, except for business ineptitude, should have been bright successes. We can heartily recommend a study of Mr. Bromley's pages. He writes in short, pithy sentences, which make his chapters very readable, and he provides a fecundity of modern instances in which purchasers have been "done," or in which they have "done" those who sought to "do" them.

The book is one of Mr. Unwin's "How To" series, which includes the "How to Arrange with Your Creditors," a guide-book which the publisher, with a delicate sense of fitness, has caused to be issued before the present book.

A new edition of Herr Gaedicke's treatise (German) on gum-bichromate processes has been issued from the publishing house of Gustav Schmidt, Berlin. In addition to providing an elementary introduction to the practice of the gum process, it chronicles recent advances in this and the allied processes, and signals the direct carbon paper of Emil Bühler as a great improvement on previous ready-made bichromate papers. The Bühler paper, we may observe, owes its properties to the use of caseine and soap as the vehicle of the pigment, but is, nevertheless, appropriately treated in a work on the gum papers proper. If we may judge from the reproduction in photogravure of one of the prints, the results hold out a successful career for the paper. Herr Gaedicke's work is sold at M. 2-50 (2s. 6d.).

## New Materials.

A new variety of their collodion paper has been issued by the Leto Photo-Materials Company (1905), Ltd., Rangoon Street, London, E.C., in the shape of "Juno" glossy mauve, a print-out paper which we are able to describe in the same favourable terms extended to the "Pluto" papers of the same firm. The new paper is intended for gold toning only, and with the bath advised by the makers—sulphocyanide and gold—gives prints of fine rich dark tones. The borax and acetate baths are also very suitable, particularly for the warmer tones. The paper is, in fact, amenable to the usual treatment of P.O.P., save that some extra care should be paid to rapid and complete drying of the prints, whether mounted or unmounted, points on which we are glad to see the makers lay special stress, as it is undoubtedly one which removes a cause of complaint sometimes made against collodion papers in general. The price of the new "Leto Juno Glossy" is on the basis of sixteen half-plate pieces per 1s. packet.

"ROTARY" Christmas Postcards.—The Rotary Photographic Co., 12, New Union Street, Moorfields, E.C., have issued postcards in "Roto," "Rotox," and "Rotograph," bearing appropriate Christmas mottoes, printed in two colours. The cards are sold at prices as follows:—

"Rotox" (Gas-light)	12	100	144
"Rotograph" (Bromide)	1/-	7/6	10/6
"Roto" P.O.P.	9d.	5/8	8/3

All users, whether amateur, professional, or photographic dealers, are advised to procure their supply immediately, as the Company's first batch of printing was considerably oversold before the cards were ready.

The Birmingham Photographic Company, Stechford, Birmingham, send us specimens of a second set of border negatives for postcard work. The set includes eight designs, and provides for the inclusion of rectangular and oval prints about  $3\frac{1}{2} \times 2\frac{1}{2}$  inches.

## CATALOGUES AND TRADE NOTICES.

MESSRS. Gold, Smith, and Co., 44, Chapel Street, Salford, Manchester, notify us that they have installed a photographic studio, with electric outfit for portraiture and printing, at the above address, where demonstration is offered to customers.

A little book on flashlight work, with a number of illustrations and diagrams, is issued by Messrs. Carl Seib, 5, Grillparzerstrasse, Vienna, I. It contains also price list, etc., of the firm's "Tip-top" flashlight outfit.

A DEVELOPER for Warm Tones.—An ex-hon. secretary of the Aberdeen Amateur Photographic Association, Geo. W. Henderson, 479, Union Street, has introduced a non-staining developer, specially suited for gaslight and bromide papers of all kinds, being slow in action and giving unlimited control. By making up a solution of 1½ ounces of developer and 4 ounces of water (reports the "Federation Journal"), you can develop fifteen postcards, and if you care you can use this same solution for the first batch of plates you are developing. To the slide maker this developer will be very useful, giving a range of tones from black, and, by using a diluted solution and increasing the exposure through brown, and rapidly to red.

SELLING Photographs in the National Gallery.—In the House of Commons on Monday last Mr. Money asked whether a number of photographic firms had established stalls for the sale of reproductions of national pictures on the ground floor of the National Gallery, and what rent was paid by those firms. Mr. McKenna replied that, in three cases, the trustees of the National Gallery had authorised the sale of photographs of pictures of the collection in the Central Hall. No rent was paid. Mr. Money: May I suggest that an opportunity is being missed of securing revenue? (Laughter.) Mr. McKenna: The matter has been considered by the trustees of the National Gallery, and I think it is a matter for them primarily. I will speak about it.

## Meetings of Societies.

CROYDON CAMERA CLUB.—Mr. C. C. E. Kenneth Mees, B.Sc., the 25th ult., gave a most interesting and instructive lecture, entitled "How Development Occurs," a full abstract of which we hope to give later.

WHITBY CAMERA CLUB.—At the annual general meeting of the above club, on Friday last, the following were elected: President, G. Wright Hodgson; vice-presidents, Messrs. Wm. Brown and Bruce; committee, Messrs. French; Horne, Gray, Botham, R. Syer, and Ross; hon. lanternist, Mr. E. Hall; assistant lantern Mr. H. A. Burnell; hon. judge and critic, F. M. Sutcliffe, Esq. hon. secretary, Woodhouse Parkinson, Ocean Road, Whitby.

SUTTON PHOTOGRAPHIC CLUB.—The annual meeting and opening of the winter session took place on the 26th ult. The report indicated that the club had considerably increased in the number of members and in the interest taken in its meetings during the year. Mr. Hector Maclean, F.R.P.S., was re-appointed chairman and Mr. C. Thwaites hon. sec. At the close of the formal business the chairman gave a demonstration of "Lantern Slide Making without a Dark Room," using for the occasion the newly-introduced "S.C.P." lantern plate of Messrs. Wellington and Ward. The proceedings connected with the handling of "gaslight" plates were outlined, stress being laid on the need for an ample exposure and an unforced development. As regards the particular plate used,

Lecturer stated that he found it almost four times as rapid as some other plates of a similar make, and that, while it took slightly longer to develop than some plates, say, twelve seconds, as against eight seconds, it was less liable to show the orange fog which certain of this type of plates were prone to when development for black tones is unduly prolonged. The developer which he employed was: Rodinal, 2 drachms; bromide of potassium, 6 grains; water, 3 ozs. This would suffice for the development of from six to twelve plates. The correct exposure for a quick printing negative, full of gradation, and yet of ample density, was one inch of magnesium ribbon burnt at a distance of twelve inches from the printing frame. Giving this exposure, a slide was produced which left nothing to desire on the score of colour brilliancy and gradation. To illustrate the plate's latitude a second was made, to which only half the above exposure was given. This turned out to be entirely clear of development fog, and, though slightly lacking in high-light details, it was fully up to the average of slides, to which the term first-rate is applied.

## Commercial & Legal Intelligence.

**CANVASSEY'S Defalcations.**—Samuel A. Barclay, of Skegby, who had been in the employ of a Bradford firm of photographers as collector and canvasser, was charged at Mansfield last week with embezzling £1 18s. 6d. Mr. R. A. Young, who appeared to prosecute, said those were not the whole of the defalcations. A fine of 40s. was imposed.

**A COPYRIGHT Case.**—Bovril, Limited, in the Second Divisional Scotch court last week, brought an action against a Glasgow postcard publisher, of a "muddle-ad." picture postcard which they consider to be an objectionable travesty of their "Alas! my poor brother" advertisement, and took action in regard to it in the Outer House of the Court of Session, Edinburgh, but Lord Mackenzie refused interdict. The Bovril Co. reclaimed, and their appeal came before the Second Division of the Court on Tuesday, October 23, the Lord Justice-Clerk and Lords Kyllachy, Stormonth-Darling, and Low being on the bench. The question was one of copyright. Lord Mackenzie's decision was based on the ground that the respondent's postcards were not intended and did not purport to reproduce the value and essential qualities or the designs of the pictures of the complainants as works of art, and accordingly were not copies or reproductions within the meaning of the Fine Arts Copyright Act, 1862. The Second Division adhere to this judgment, and found the Bovril Co. liable in expenses.

**PHOTOGRAPHIC Trade Mark Action.**—In the Chancery Division of the High Court of Justice last week, Mr. Justice Neville had before him a motion in the action Kodak (Limited) v. J. Lancaster and Sons (Limited), by which the plaintiff's asked for an injunction to restrain the defendants, of Colmore Row, Birmingham, from infringing the plaintiff's registered trade mark, "Brownie." Mr. Murphy, for the plaintiffs, said an agent of his clients in July handed a written order to defendants' servant for "one Brownie film, 7d." In response to that order, an Ensign film, wrapped up in paper, was supplied. This was pointed out to the defendants' manager, and he said it was a mistake, and apologised. On a writ being issued, the defendants offered an undertaking in the terms of the writ and to pay the costs of the action up to that date, but stated, if the proposal was not accepted, that they would be prepared to defend the action. The defendants' counsel was not instructed to consent to put an end to the action and to pay the costs, and the motion was ordered to stand over till the trial.

**HULL Bankruptcy.**—At the Hull Bankruptcy Court last week the case of Richard Chorley Garside, photographer, lately residing at 106, Anlaby Road, and now at 2, Charles Street, Hull, came before the Registrar. Gross liabilities were £1,409 4s. 7d., expected to rank £1,388 12s. 7d., assets £226 3s. 6d., and deficiency of £1,362 9s. 1d. The debtor attributed his failure to "illness and want of capital." He said that he commenced business in Long Eaton in 1893 with a capital of about £140. In February, 1905, he sold the business for £40 and came to Hull. He took over the business, 106, Anlaby Road, as a going concern, and paid £280. He also took over the lease, and in August this year the lessor took possession for a quarter's

rent. Mr. C. G. Smith, a friend, advanced him the money for the ingoing, and had since lent him £800 or £900. Mr. Smith became his guarantor under the lease, which was running for eight years. In August last year he opened a shop in Chariot Street under the name of the "Star Photo Company," and closed it in September this year, and in November, 1905, he commenced a branch under the same name at Grimsby, and closed it in March this year. Smith advanced the money for these shops, neither of which earned a profit. At Grimsby he paid a man a salary of £2 10s. a week, but the weekly takings did not average that amount. Smith was not a partner with him, but occasionally advised him. He (Garside) became aware of his insolvency two months after he commenced business in Hull. In August this year he handed his stock-in-trade and furniture to an auctioneer, and after certain charges had been paid, £1 0s. 9d. had been handed to the Official Receiver as the net result of his trading. His wife and his late assistant were now carrying on business in Charles Street, and he was advising them. He could not dispute Mr. Smith's claim as to the amount advanced. He had never been in a position to pay creditors, and had always relied on getting money from Mr. Smith. When he was running his three shops the rent was £238, the rates would be over £60 a year, he was paying wages of from £7 to £9 10s., and his gross profits were £200 a year. He was unable to get out of the lease of the Anlaby Road shop. He denied that excessive drinking had contributed to his insolvency. The examination was closed.

**THE Tabloid Trade Mark.**—In the High Court, Chancery Division, on October 29, before Mr. Justice Swinfen Eady, the application of the Capsuloid Company to register the word "Tablones" was heard. The motion arose out of a refusal by the Registrar to register the trade mark in question on the ground of similarity to another mark ("Tabloids," the property of Messrs. Burroughs, Wellcome, and Co.), already on the register. The refusal was upheld by the Comptroller and by the Board of Trade, to whom this appeal was referred to the Court. Among the affidavits read, the deponents being afterwards cross-examined, was one by Dr. Dixon, who is the principal shareholder and the managing director of the Capsuloid Company. His evidence was that he had invented the word "tablones," which, he said, indicated not only the form but the composition of the medicine, where as "tabloid" meant only the form and required the addition of some word to indicate what kind of tabloid was meant. There need, he said, be no confusion between the two; indeed, out of many thousands of orders received by the company, there were none showing such confusion. The company had been spending £1,000 a month in advertising their medicine, which was a proprietary article, and their show cards and other advertisements left no doubt of the distinction between tabloids and tablones. Mr. Justice Swinfen Eady, in his judgment, said: It appears that the word "tablones" has been in use for a little over three years. Messrs. Burroughs, Wellcome, and Co., who oppose the application, say they first heard of it in October, 1903. "Tablones" is used in connection with a preparation said to be valuable in cases of indigestion. According to the evidence, "tablone" is the name applied to the particular medicament so made up, and which is sold as a patent medicine, the particular affection for which it is said to be good being stated on the aluminium boxes which contain it. Notice of the application was given, and it is opposed by Messrs. Burroughs, Wellcome, and Co., the main ground being the same as that on which the Comptroller based his decision—namely, that the last-named firm's mark is registered in the same class (Class 3), and that Section 72 (2) of the Patents, etc., Act, 1883, says:—"The Comptroller shall not register with respect to the same goods or description of goods a trade mark so nearly resembling a trade mark already on the register with respect to such goods or description of goods as to be calculated to receive." Evidence has been given by retail and dispensing chemists as to how tabloids are asked for by their customers, and it shows that when they are asked for, reference is made not invariably to the medicines which they contain, but often only to the ailment for which they are required, such as tabloids for headache, for indigestion, and the like. Again, tabloids have been named in written orders given to the Capsuloid Company by persons who evidently intended to order tablones, as was shown by their attaching to their orders coupons from newspapers in which the latter word was printed. On the other hand, orders for tablones have sometimes been sent to Burroughs, Wellcome and Co., who have passed them on to the Capsuloid Company. There

is no explanation why the name "fablone" was adopted—at the same time it would seem when litigation was in progress relative to "tabloids," but perhaps in ignorance of that litigation. On the whole, I am satisfied that there is that resemblance between the two words as is, in the words of the statute, "calculated to deceive." The Registrar having declined to proceed, the burden is on the applicants to show that the mark is one that ought to be registered. Not only have they failed to do that, but their opponents have shown that it is one so nearly resembling another on the register as to be calculated to deceive. I am therefore bound to uphold the Registrar's decision, and, without referring to other grounds, which might be stated, I dismiss the application, with costs.—"Times" report.

**THE KODAK DIVIDEND.**—The Eastman Kodak Company have declared an extra dividend of 5 per cent. upon the common stock of the company, payable on December 1, to shareholders of record on October 31. This dividend makes the second paid this year, the first being 2½ per cent. in April. Thus, with the usual 10 per cent. rate added, the stockholders will do very well in respect of 1906, even if they get nothing more. In 1905 the extra dividend paid was only 2 per cent., making 12 per cent. altogether for the year. In the circumstances it is not surprising that the \$100 shares rose \$15 to \$195 on Monday.

## News and Notes.

**POSTCARD CONCESSIONS.**—New regulations respecting postcards have come into force this week. In addition to the postage stamps and the small address label already permitted, the Postmaster-General will allow the public to attach to a postcard a gummed label, not exceeding two inches in length by three-quarters of an inch in width, bearing the name and address of the sender of the card; also engravings, illustrations, drawings, and photographs on very thin paper, provided that they are completely adherent, either on the back of the card or on the left-hand half of the address side. The new regulations apply to postcards of all kinds, whether sent to inland, Colonial, or foreign addresses. Single postcards of private manufacture addressed to places abroad will no longer be taxed in the British Post Office on account of the omission of the title "Postcard."

**"AITCHISON" Prizes for Optics.**—The Optical Society has accepted the offer of Mr. James Aitchison to present prizes to the value of five guineas to encourage junior members of the trade to study the instruments in which they deal, from the point of view of the user's requirements and convenience. Five prizes each of the value of one guinea will be awarded for essays, to be sent in not later than March 1, 1907. The prizes are open to all under the age of 25 engaged in the optical industries. Candidates are allowed to select their own subjects in the following groups:—(a) Telescopes, (b) microscopes, (c) photographic apparatus, (d) meteorological instruments, (e) any other widely used scientific instrument dealt in by opticians. Candidates will be expected to treat the instrument selected from the user's point of view, and to indicate the various directions in which they can be used in the arts and ordinary processes of trade. Candidates will also, if they desire, be allowed to select a particular trade or industry, and show how and what scientific instruments can be used in it. The society reserves the right to withhold one or more of the prizes if essays of sufficient merit are not sent in. All essays should be sent to Mr. S. D. Chalmers, Hon. Secretary of the Optical Society, 20, Hanover Square, London, W., not later than March 1, 1907.

Mr. HAROLD HOOD writes us as follows, in reference to the patent specification of his abstracted in our issue of last week:—"In the current number of the BRITISH JOURNAL, in your 'Summary of Contents,' in referring to my patent, you describe it as 'A new type of full-size focussing finder.' As this is likely to be misleading, even when read in connection with the abridged specification given in the same number, I should be much obliged if you could find space to allow me to state that this invention refers to a focussing finder whose chief advantage is that it need not necessarily be full size, but half or three-quarters, or any other convenient size, as tending towards much greater portability and lightness than the usual box form reflector.

## Correspondence.

*\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*\* \* We do not undertake responsibility for the opinions expressed by our correspondents.*

### FIRELIGHT PHOTOGRAPHS

To the Editors.

Gentlemen,—In reference to your paragraph on "Firelight Photographs" this week, I beg to inform you, as I have also the "Daily Mail," that about 6 or 8 months ago I introduced exactly this style of photograph, a specimen of which I have pleasure in enclosing.

With regard to the price, no doubt the ones at £7 7s. a dozen are carbon on yellow or orange supports, but the one I am sending is simply a glossy bromide print stained by immersion in "Bertha orange."

We are charging £2 2s. a dozen for these.

No doubt the idea is not by any means a new one, although I have never seen them in the profession before as ordinary commercial work.

Three specimens of this sort of work have been shown in our window for at least 6 or 7 months, so that it can hardly now be called a new thing.—I am, yours faithfully,

H. ESSENHIGH CORKE.

39, London Road, Sevenoaks.

[The prints sent by our correspondent are highly realistic.—EDS., B.J.P.]

### PHOTOGRAPHS FOR ADVERTISEMENTS.

To the Editors.

Gentlemen,—Now that the summer season is at an end, and your readers are looking over their prints, will you allow me through your columns to invite them to consider same from an advertiser's point of view, and decide for themselves how far they can be made use of by manufacturers for advertising purposes.

I am prepared to purchase good photographs of subjects suitable for reproduction in advertising. Any size will do, and the prints may be in any process sufficient to emphasize the idea the photographer wishes to convey. I will pay good prices for good subjects. A simple and direct idea that tells its own story right away is what I want. They should not illustrate one firm's specialty, but should apply generally to any particular article of consumption, for wear or other use, without being identified with one maker. It is impossible for me to say here what is the best subject for advertising, for the photographer can only judge this by studying advertisers' methods for himself.

I will carefully consider any photographs submitted to me, and will promptly return any that are unsuitable, if stamps for postage are enclosed, and I will say why I think them unsuitable.—Yours truly,

CHAS W. WALKER.

McCaw, Stevenson and Orr, Ltd.,

Advertising Contractors, 31, Shoe Lane, E.C.

October 26th, 1906.

### THE P.P.A. EXHIBITION.

To the Editors.

"Very like a 'wail.'"—Shakebacon.

Gentlemen,—Oh why, and oh why, did we ever allow the energetic officials of the P.P.A. to persuade us to send samples of our everyday work to their exhibition. Before we did so, many of us thought our productions meritorious, or to say the least, passable. Now our eyes are open and we know the terrible truth; we have been severely snubbed by irresponsible amateurs, and have been made to realise our utter insignificance. We have found our level, and, according to the majority of our critics, a very low level it is.

Well, "grieving is but folly," although we cannot help feeling acutely that we have been humbled, sat upon, and squelched. Still, we have one little consolation, the public appreciates and is willing to pay for such work, which probably is more than could be said for the everyday work of most of those who have criticised us so unkindly.—Yours truly,

London, October 29, 1906.

AN EXHIBITOR.

## Answers to Correspondents.

**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.**

**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**

**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.**

**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

### PHOTOGRAPHS REGISTERED:—

**Wright, Grosvenor Studio, Church Road, Upper Norwood, S.E. Two Photographs each of Sir W. P. Treloar and Lady Treloar.**

**Ca decott, 24, Regent Street, Wrexham, North Wales. Photograph of Mr. and Mrs. Gladstone's Memorial in Hawarden Church.**

**Garrett, 13, High Street North, Dunstable, Bedfordshire. Photograph on the Front Page of a Menu Card.**

**Pickup, 1, Ivy Grove, Rawtenstall. Two Photographs of the Goodshaw Brass Band.**

**Ward, 2, Victoria Road South, Southsea. Photograph of the Interior of St. Bartholomew's Church, Southsea.**

**Macmillan, Ravelston Elms, Murrayfield, Edinburgh. Photograph from the Front Model of the Statue of John Knox in St. Giles' Cathedral, Edinburgh.**

**A. Matelli, 72, St. James' Street, Walthamstow. Two Photographs of the Linton Football Club, Season 1906-7.**

**Smith, St. Mary Bourne, near Andover. Photograph of an Abnormal Pig, same having an Elephant's Trunk, Mouth of a Human Being, Goggle Eyes, and a Bony Free from Bristles.**

**P. Cummings & Co., 54, Albert Road, Middlesbrough. Two Photographs of the Middlesbrough Football Team and Directors, 1906-7.**

**W. Jackson, South Dene Studio, New Barn Lane, Rochdale. Photograph of Old Racker, Rochdale. Photograph of Church Style, Rochdale.**

**MARSHALL.**—If praise is helpful to you, we might say that, in our opinion, the cattle have been taken at a moment when they were in a most advantageous position for pictorial purposes. They make excellent lines, they give points of various distances where the landscape without them would have been poor in vertical planes, and they add a great interest of colour and accent to the view.

**"Assistant"** will send his name and address (not for publication) we will reply to his query.

**"Glasgow"** will send his name and address (not for publication) we will reply to his query.

**S.—I.** The spots are, we believe, due to metallic particles in the hypo bath. These are more likely to be met with if an acid fixing bath is used. We should advise filtering the bath through one or two thicknesses of flannel.

**PREHENSIBLE PROCEDURE.** — I received an order from a young woman, over age, home with her parents, for an enlarged portrait of her father, from a carte de visite given me. When done, I canvassed orders with same, in their village (and openly), without permission. Next morning I received a letter from the father. Asking who authorised me to do so, stating it plainly showed me up, and what I was, and demanding the return of the original photograph, when I at once destroyed the said enlargement (and returned the photograph as desired), and sent him (the father) the bill for the enlargement. Now, the daughter demands the order executed, having paid nothing on it, and the mother remarking (in the presence of a witness) that I was anything but straightforward, when I had openly canvassed with the said enlargement, even directly opposite their dwelling. Kindly oblige me the best to do at your earliest. — **PORTRAIT.**

Your action was most reprehensible. You had no right what-ever to take about an enlargement you were commissioned

to make. Again, it was a piece of impertinence on your part, after destroying it, to send a bill for it to the father, who did not order it. We are not at all surprised at the mother expressing her opinion of your action. You ask us what is best for you to do. It is that you tender a respectful apology to the family for the unwarrantable use you made of the portrait.

**ACCESSORY WANTED.**—Will you kindly let me know if I get an accessory made (not background) of crescent moon, would I be at liberty to use it, or is it a patent? — **DOUBTFUL.**

We should doubt if the accessory is stocked by anyone. Such houses as Houghtons', Marion's, and others that make a specialty of photographic accessories, would get it made to your order if you supply them with the design. Failing that, you will be able to get it made by those who make theatrical properties. Or it ought not to be very difficult for a local carpenter to build you one, utilising a tall pair of steps (draped), on which the sitter is posed, the "moon" being suspended so that the subject appears to be seated on it.

**J. K. (Carrahan).**—The lamp is to burn methylated spirit. There are several such on the market. Messrs. Houghtons and Messrs. Butcher each supply one.

**J. H. J.**—There is nothing we can do except to suggest that it is barely possible that the makers would be glad to have the plates placed in the hands of an expert, who would report upon the results now obtainable in them.

**PORTRAIT OF WELLINGTON.**—Can you tell me where I can procure a good portrait or print of Wellington (the Iron Duke), with liberty to reproduce? — **IRON DUKE.**

London Stereoscopic Company, Regent Street, London, W.; Mansell and Co., 405, Oxford Street, London, W.; or Augustin Rischgitz, Linden Gardens, Bayswater, W.

**LETTERING ON POSTCARDS.**—Will you kindly inform me, through the columns of your paper, the procedure to obtain printed matter on postcards? — **RAGLAN.**

The matter is set up in type and photographed on to wet collodion or a process plate, which is then stripped off and laid on the glass bearing the picture negative, and surrounded by a clear margin. Any clear parts not covered by the transferred negative are then blocked out so as to print white.

**SITUATIONS ON THE CONTINENT.**—I want to get a situation as operator-retoucher or general assistant in Madrid or Italy. Will you kindly advise me what to do to enable me to get to one of these places? — **A. F. S.**

We can only suggest that you advertise in one of the Italian photographic papers, say, the "Corriere Fotografico" (Dr. C. Zarghieri, Piacenza); or in the "Photos," Calle de Alfonso I, 19, Entresuelo.

**J. B. W.**—O. Sichel and Co., 52, Bunhill Row, E.C.; and A. W. Isenthal, 85, Mortimer Street, London, W.

**C. E. W.**—We should say 30s. is an average figure.

**FERROTYPE EMULSION.**—I shall thank you very much if you will be kind enough to tell me how to make an emulsion for making ferrotype dry plates. I have used all the makers' plates I know and find that they are very slow and make a poor picture, and do not in any way come up to the wet plate ferrotype picture in speed or detail. — **PHOTO.**

A collodion emulsion is used, probably somewhat similar to that for transparencies, on page 968 of the ALMANAC, but we cannot say precisely.

**LENS QUERY.**—I have a (Jamina, of Paris) portrait lens offered me. It has about 3in. or 3½in. diameter lens; it seems to give very fair image, etc. Have you any idea what it should be worth or what they are new? Nobody seems to know anything about this maker, and these people that have it will not say what they want for it. They want me to make an offer, and I would like to know what it is worth now or what its value was new. Thanking you in anticipation. — **HUDDERSFIELD.**

We do not know the name of Jamina. There was Jamina, of Paris, and if the lens is by him it is a very old one, as he has been out of the business for very many years, being succeeded by Darlot. Jamina's lenses, as cheap lenses, were in

fair repute in the sixties. But they have but little commercial value at the present time. The original list price of the above size, we think, was something like 100 francs or less, equal to £4 English. We should advise you to try the instrument and offer what it is worth to you, supposing it answers your purpose. See note on "Ancient Lenses," on page 842 of last week's issue.

**L. R.**—You will require a light of from 1,500 c.p. to 3,000 c.p. in the aggregate. The Adamson pressed gaslight (W. M. Still and Co., Charles Street, Hatton Garden, E.C.) or the Tress gas installation (206, Oxford Street, W.) should answer your purpose.

**CHEMISTS.**—You had better apply to any of the houses who undertake cinematograph entertainments, such as Sanders and Crowhurst, Shaftesbury Avenue, London, W., or Archer and Co., Lord Street, Liverpool.

**COPYRIGHT.**—Would you be good enough to give me your opinion on the copyright involved in the following case: A photograph is handed me for copying and enlarging, having been loaned by the subject thereof (and, therefore, presumably the owner) for that purpose. The photograph is of a public man, and the enlargement for presentation. The original copy bears the name of an American firm, and is embossed on corner of the print "copyright." Can you tell me whether they have any rights in the reproduction, or do they pass to the purchaser?—W. B. WOOD.

Most probably the photograph was paid for, and the copyright is, therefore, vested in the person who gave the order—the subject of the portrait in this case—and you may, therefore, carry out the instructions. In any event, it is unlikely that an American photographer has a copyright in this country, because, as America does not subscribe to the Berne Convention, an American photographer has to take special steps to secure "copyright" here.

**FLASHLIGHT.**—1. The best and most economical flashlight for photographing animals, and where procurable? 2. The name and address of a cat fancier or trainer for photographic purposes?—T. GILBERT.

1. We should advise you to select one of the larger flash-lamps, such as you will see in the lists of Houghtons, Fallowfield, and other large dealers. See also our advertisement pages. 2. We know of none. Better apply to journals such as "Fur and Feather."

**COLOUR-GRAPHY.**—I should esteem it a favour if you would inform me whether there is a book published on three-colour work; and, if so, who is the publisher? I should like, if possible, a book dealing with one method—for preference, the one in which carbon prints are super-imposed on each other.—**COLOUR-GRAPHY.**

Messrs. Dawbarn and Ward, 6, Farringdon Avenue, London, E.C., publish the latest book on the subject—viz., "Natural Colour Photography," by König and Wall. The carbon and other processes on paper will form a feature of the forthcoming "Almanac."

**BOOK ON RETOUCHING.**—Can you recommend me where to get a book of instructions in retouching?—R. R.

"Retouching," by Arthur Whiting (Dawbarn and Ward, 1s.), or "Practical Retouching," by Crinkwater Butt (Iliffe, 1s.).

**PLATINUM PAPER.**—Some years ago I tried some daylight printing paper, similar to platinotype, that required hanging in damp air or holding over boiling water to fully develop. I cannot remember either the name of the paper or that of the maker; and should be much obliged if you will let me know, through your "Answers to Correspondents" column, whether you know of such a paper, and, if so, whether the image is formed of iron or platinum?—P. DOUGLAS.

The paper to which you refer is not, we think, made now, but a very similar one is now supplied by O. Sichel and Co., 52, Bunhill Row, E.C. The image is in platinum.

**PORTRAITURE.**—I should feel much obliged if you would kindly reply to the following: I have a room 16ft. by 12ft. and 10ft. high. Is this large enough to take half-plate photos with a

10in. Zeiss planar lens, with electric arc lamp? Would photographs be fully equal to ones taken in a studio?—P.

The room will do very well, but you will not be able to take full-length portraits of the cabinet size in it with a lens of focus. It will do all right for busts and three-quarter length portraits. Very good portraits are taken with the arc light.

**ALUM BATH.**—1. We shall be greatly obliged if you can tell us what is the cause of the water turning slightly milky, after printing in postcards which have been toned and fixed, given changes of water, and then put in the alum bath for 2 minutes. It only happens with the first change after the bath. Will it affect the permanency of the cards? 2. Can you tell us where we can get the pens, etc., for tinting postcards (jewelling outfits, as they are called). Thanking you in anticipation.—LEWIS BROS.

1. The cause of the milkiness is that the hypo was not washed out of the prints, and the alum has decomposed it and precipitated sulphur. It will certainly affect the permanency of the prints. The hypo should be thoroughly washed out of the cards before they are put into the alum bath. 2. Such as Fallowfield's supply the outfits.

**SAFELIGHT.**—Measure the area of your tank, not the cubical content, and to every square inch allow one-tenth grain tartrazin and one-twentieth grain rose bengal, dissolved in distilled water.

**THE Polytechnic Classes.**—The prospectus of the classes of the Photographic School at Regent Street Polytechnic reaches us a few days before the report of the City and Guilds of London Institute, from which we see that the first-class certificate and medal in the examinations in May last were taken by Mr. Hewitt, of the Polytechnic teaching staff, in the department of pure photography, and by Charles T. Hynam, a student at the Photographic School in the process section. Mr. Howard Farmer points to a long list of successes antecedent to these, and to even more gratifying records of his students in technical portrait photography for commercial purposes. The programme of classes in negative making, operating, printing, retouching, finishing, and colouring, and also in photo-engraving and photo-lithography provides a course of instruction and improvement which cannot be too largely utilised by all those earning their living by photography.

**THE Scottish Salon.**—We have to announce that the "foreign" section of the forthcoming Scottish Salon will be contributed by Mr. C. F. Inston, of Liverpool, who will exhibit about fifty of his photographs. A number of Austrian and German works collected by Herr Masuren, will also form a section of the "Scottish Salon."

With the issue of January next (to appear before Christmas) the "Process Photogram" is to be made a separate publication on an enlarged scale. The subscription price is also to be lowered, and increased facilities provided for the full representation of the photographic arts. Our contemporary has occupied a world-wide sphere of usefulness in the past, and we wish it every support in its expansion.

**NOTICE TO ADVERTISERS.**—Blocks and copy are received for the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The exhibition of photographs by members of the Professional Photographers' Association, now open at the BRITISH JOURNAL, closes to-morrow (Saturday) at 12.30. The small gallery will reopen until the New Year.

A method of development, the salient feature of which is the recent state of the solution, has been advocated by a German author, and commended by Dr. Neuhauss. (P. 884.)

Mr. Harold Baker details the complete reversal of ordinary practice which must be observed in order to succeed with the "art" gaslight paper. (P. 887.)

Mr. J. McDowall, in the "Chemical News," has demonstrated the action of tropical heat in fogging plates by promoting emanations in the dark-slides. (P. 891.)

Read in self-toning emulsions, a method of colouring photographs, and a modified Thornton-Pickard shutter are among the patents of the week. (P. 895.)

A correspondent in New South Wales, Mr. J. H. Homan, discusses the rules for constructing a focussing scale given in the BRITISH JOURNAL OF PHOTOGRAPHY for June 1 last. (Pp. 888-889.)

A recent conviction of a tradesman for a false description of goods should warn those who would supply bromide or gaslight photographs as platinum prints. (P. 892.)

Suggestions and advice on Christmas work by a country professional are given on page 889.

Some aids to copying are offered to those who have occasional orders for this kind of work in their business. (P. 893.)

A great international exhibition of photography is to be held in Germany in 1910. (P. 896.)

The Royal Photographic Society's new lecture room was opened Tuesday evening by the Earl of Crawford. Photographs of the new room, and a report of the conversazione which marked the occasion, appear on page 892.

## EX CATHEDRA.

### Variations of Aperture in Lenses.

There seems to be a very common belief that if the aperture of a lens is measured for distant objects, i.e., for parallel light, the result is a constant value that can be applied in estimating exposure on near objects. For example, a lens of, say, eight inches focal length is tested in the usual way by placing a pin-hole at the principal focus with a light behind, and measuring the diameter of the parallel beam emergent from the lens. If the diameter of that beam is one inch the lens is stated to have an effective aperture of  $f/8$ , and it is assumed that its aperture is still one inch, or equivalent to  $f/16$  when copying on a scale of full size. In many cases this assumption is entirely wrong, and if the lens is used for enlarging, serious errors in exposure may result if exposure is calculated on the basis of a one-inch aperture. The errors may occur as the result of estimating the relative exposures for different scales of copying, or, more commonly, by ignoring the direction in which the lens is turned. It is possible in the case of enlarging for the aperture to be equal, say, to  $f/9$  when the hood of the lens is towards the negative, and  $f/8$  when the hood is towards the enlargement. This causes exposure to vary in the ratio of 5 to 4, and even such a small variation may be of importance. It is, however, possible for the variation to be as much as 2 to 1, in which case the matter is certainly serious. It is very difficult to allow for such variations, and the safest procedure is to select lenses of fairly constant aperture for enlarging purposes. They are very readily tested by measuring the aperture in the way above described, first with the lens hood directed away from the pin-hole screen, and then with the lens reversed. If the results are the same the aperture may be considered to be constant for all distances of the object, but if the results differ the aperture is certainly inconstant, and the proper exposure can only be safely determined by trial, not by calculation. Some recent tests on modern non-symmetrical anastigmats showed that with one lens  $f/6$ ,  $f/8$ , and  $f/11$  became  $f/6.8$ ,  $f/9.1$ , and  $f/12.5$  when the lens was reversed. In another case  $f/6.5$ ,  $f/8$ , and  $f/11$  became  $f/7.2$ ,  $f/8.5$ , and  $f/11.5$ .

\* \* \*

### Angular Aperture.

The matter of angular aperture is one that is either strangely ignored, or confused with that of effective aperture. It should be more generally understood that, while effective aperture governs exposure, angular aperture governs depth, and the two quantities are not always, or even often, quite the same. The method of measuring effective aperture has already been described in a preceding paragraph on "Variations of Aperture in Lenses," and it is fairly well known. The

measurement of angular aperture is not quite so simple without apparatus, but the following method, due, if we remember rightly, to Dr. Drysdale, is perhaps the most suitable for ordinary photographers:—Focus sharply on a distant small source of light. Then rack in the camera for a definite known distance, and measure the diameter of the disc, which then represents the distant point of light. If the former dimension is divided by the latter one (i.e., by the diameter of the disc), the  $f$  value of the angular aperture is obtained. If this value is then used in all calculations concerning either depth of field or depth of focus the results will approximate to the true depths available more nearly than any results obtained by using effective aperture as the basis of calculation. As a strict matter of fact, effective aperture and depth have nothing to do with each other, excepting in the case of the hypothetical ideal lens of the text books. Some actual lenses under particular conditions may behave very nearly as the ideal lens is supposed to do, but such cases are so very rare that they may be almost ignored. It may be observed that the old-fashioned R.R. lens generally behaves most nearly like the ideal lens, as its effective and angular apertures do not generally differ very much. In the even older single-view lens the angular aperture is smaller than the effective aperture, while in the modern anastigmat it is generally greater, and the popular idea that anastigmats give less depth than R.R. lenses, and the latter less depth than view lenses, is due, in part, to calculating the depth from the effective instead of the angular aperture.

#### Varnishing Negatives.

In the days when heavily-sensitised albumen papers were almost universally employed it was essential that every negative should be coated with a protective varnish if irremovable silver stains on the gelatine film were to be avoided. Nowadays, when the silver is more thoroughly incorporated with the vehicle, gelatine or collodion usually, in the form of an emulsion with which the paper is coated, this danger of staining is much less, though it is by no means altogether absent. Varnishing has to a great extent been left undone in many businesses as a consequence. It is forgotten that silver processes are not the only ones which may give rise to stains on the negative. Both platinum paper and carbon tissue will produce stains if the gelatine film of the negative happens to be sufficiently damp. In regular printing, of course, every care is taken to keep everything as dry as possible, so that the danger principally lies in the direction of a negative carelessly left out all night or during a shower of rain. The risk of staining is, however, very

much diminished even under these circumstances if the negative has a protective coating of good spirit varnish. For portrait negatives varnish is usually needed, if as a protection for the retouching on the film, which may be partially removed by frequent dusting, then as a means of supporting more pencil work than can be got upon medium-coated gelatine. From the printing point of view we believe it is generally recognised by the most experienced workers that a negative is not improved by varnishing, certainly in the case of very thin negatives the shadow detail tends to print less strongly after varnishing. Negatives may with advantage be left unvarnished, and protection a thin sheet of clear celluloid placed between the negative and the printing paper.

#### A New Method of Development.

The article which we publish elsewhere will, we trust, attract the attention of some of our readers who are in a position to give us evidence, confirmatory or otherwise, of the author's contentions. Dr. Neuhauss' comments are mistakable, and comparative trials could be carried out by anyone. If the author is correct in his statements, it is obvious that his method should give two totally different curves from strips exposed in a Hurter and Drift machine, and comparative readings would be of considerable interest. The method, if practicable, would be of special value in quick shutter work, as well as in those bad halations, the amelioration of which Dr. Neuhauss reports upon very favourably. Theoretically the process is an ideal one, but to carry it out to perfection in practice would entail, we think, the use of separate dishes for each plate, and dishes, too, which are actually flat on the bottom, a condition which is not easy to fulfil by purchase in the ordinary way.

\* \* \*

#### False Trade Descriptions.

There are, we are sorry to say, a number of professional photographers who do not hesitate to supply in the place of soft and black platinum prints photographs which are actually black or toned bromides or gaslight prints. We have from time to time pointed out here and in answer to correspondents that by so doing they laid themselves open to prosecution. Quite recently a tailor was sentenced to months' imprisonment in the second division for selling "Harris Tweed" a suit of clothes made from material manufactured in Huddersfield. On an appeal to the Sessions it was held by the appellant's counsel that the Brussels carpet and Worcester sauce need not necessarily

### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1907.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-sixth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,616 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1907 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### THREE-COLOUR PHOTOGRAPHIC PRINTING PROCESSES,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1907 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1907 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, and, wherever practicable, features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—Our publishers ask us to inform Agents that it will be as well to place their orders for copies immediately, as the issue is always booked before publication, and a second edition will not be printed.

be made at those places, but the Commissioner, while reducing the sentence from one of imprisonment to a fine of £20 and costs, was clearly of opinion that a false or misleading description of goods had been given. We commend the instance to the notice of photographers, for while in many cases, even if the customer were certain he had not been supplied with goods in accordance with the description on his receipt, no action at law would result, yet it is quite possible that some irritated client, or a man to whom a prosecution would be an interesting diversion, would take proceedings such as were instituted against the tailor; and, dismissing the question of imprisonment, the sum represented by a heavy fine and costs would go far to pay for platinum paper for manufacturing the genuine prints. This, of course, is looking at the matter simply from the £ s. d. point of view, and there is still the question of business integrity and the discredit brought on the whole profession by the irregularities of some of its members.

\* \* \*

#### Cause of Spots on Prints.

Spots on prints come from many causes. There is one kind of spot that seems to be very prevalent during the winter months that is rarely seen at any other season; we allude to minute yellow ones, that seem to make their appearance a few days, or maybe weeks, after prints are mounted. Sometimes they have a nucleus and sometimes not. Colloidio-chlorides, or, as they are often termed, "C.C." prints, appear to be more prone to them than those on some other papers. In the article last week on "Warming the Studio" (see page 864), we alluded to the deleterious effect that the particles of fine ash, to which the fuel used in the slow combustion stoves is consumed, may have on moist prints if exposed to them. On a recent morning we were in a studio which was warmed by one of these stoves of the enclosed form. The fire, we learned, had just been lighted, and round the stove, on blotting-boards, were laid a number of freshly mounted prints to dry. The floor had just been swept, and the things in the studio were at the time being dusted. Now, it is very obvious that some of this dust must have found its way on to the prints, and as the fuel used in the stove was coke, the fine dust was largely composed of sulphurous compounds. What wonder, then, if the prints in the near future should develop small spots, while the actual cause of them would not be suspected. As we said last week, when these stoves are used, the precaution should be taken that the fine ash should be moistened before it is raked out, so that dust is avoided, and even when that is done prints should not be exposed in the place until the slight dust that is unavoidably created has completely subsided.

\* \* \*

#### A Further Note on Ancient Lenses.

In "Ex Cathedra" (see p. 842 *ante*) we advised buyers of old portrait lenses not to complete the purchase before trying them. Now, it may happen in testing some of them that although the image may appear perfectly sharp on the focussing screen, the picture, when taken, is very unsharp. This is due to the lens not working to focus, *i.e.*, the actinic and visual foci do not coincide. All the earlier portrait lenses of Voigtländer, and copies of them, were made with the chemical and visual foci non-coincident, consequently after the image had been focussed the lens had to be racked out a certain distance to obtain it sharp in the negative. Usually there was an engraved scale on the inner tube of the mount to show the difference between the two foci. In some there was merely a line near the hood of the mount, and in others no indication at all. It was the late Mr Andrew Ross, if we

mistake not, that first put portrait lenses of the Petzval type on the English market in which the visual and actinic foci were coincident. All the early Ross lenses do work to focus. It does not follow, however, that because a lens does not work to focus that it is not a good one. Indeed, when Voigtländer put lenses on the market in which the two foci were coincident he did so somewhat under protest, as he maintained that they were better separate. Lenses that do not work to focus are somewhat inconvenient in use, as an adjustment has to be made after the image is focussed, and the difference between the two foci increases as the camera is brought nearer the subject. This inconvenience increases greatly if the instrument be used for copying purposes.

\* \* \*

#### The Recent Postal Concessions.

The new regulation with regard to postcards should be advantageous to some photographers. Hitherto nothing has been allowed to be attached to a postcard except the postage stamp. Now a gummed label, not exceeding 2 in. by  $\frac{3}{4}$  in., may be stuck on. Also photographs, or other pictures, if they are on very thin paper, may be mounted on either the plain side of the card or the left hand of the address side, provided they are perfectly adherent. This should give an impetus to the business of those who make a feature of midget and stamp portraits—sometimes called "sticky backs"—particularly if the backs of the pictures are coated with an adhesive such as that on postage stamps so that they are easily applied. We imagine that a much thinner paper than that usually employed for this class of picture, which is generally a thick bromide, will be necessary, as the regulations specify *very thin paper* for the pictures (the italics are ours). This concession applies to postcards of all kinds, whether sent to inland, colonial, or foreign addresses. We have no doubt that the new rules will also give an impetus to the trade in mounts to be used as postcards, the sale of which hitherto has been kept down by the penny stamp required if the mount carried out its legitimate purpose of bearing a photograph.

#### • COPYING.

In the majority of portrait studios there is a considerable amount of copying to be done, work which is in too many cases approached in an unsystematic way, and which, as a consequence, is done neither so well nor so quickly as it might be otherwise. It is in the selection of apparatus and in the making of the adjustments of the same that opportunity occurs for saving a good deal of time and labour.

The work is too often done by an assistant, with the ordinary studio camera and lens, apparatus which may be admirable for its own special purpose, but which is not by any means the best for copying. A very important matter, the maintenance of parallelism between the original and the plate is very difficult of attainment, and though measurements may be taken from the sides of the camera front to the corresponding sides of the copyboard with a piece of string it is a tedious and time-wasting procedure, as fresh measurements are needed every time the camera is moved nearer to or further from the original. The portrait lens is most unsuitable for copying from the flat on account of its very curved field, a small stop being necessary if good marginal definition is to be obtained. With portrait lenses it should be noted the use of a small stop employed to flatten the field is likely to produce flare spot. The most simple arrangement will be to employ a stout copying board, say of 6 to 10 feet in length and 11 inches in width, fitted with a sliding easel, which may easily be constructed of a good-sized drawing-board. The advantage of having

this made to slide is that when working with a lens of short focal length the camera may be kept at or near to the operator's end of the copying board while the easel is slid along the board towards the camera. Focussing is then much easier than when two or three feet of board has to be reached over in order to examine the image on the ground glass.

In order to bring the lens opposite the centre of the copyboard or easel, the camera should be mounted on a sliding saddle, which may be a wooden box of about 8 or 10 inches in height, provided with two strips of wood nailed to the underside. It is then easy to attach a landscape camera to this box by means of the ordinary tripod screw, and the saddle carrying the camera may be slid nearer to or further from the easel bearing the original, while accurate parallelism is maintained. If the landscape cameras are frequently in use, there should be no difficulty in picking up an old 10 x 8 or larger size camera of the square bellows type, focussing from the back, many of such old pattern instruments being offered for sale by the secondhand dealers at almost nominal prices. Probably a suitable lens will be at hand, an anastigmat answering the purpose best of all, though a good rapid rectilinear if stopped down to  $f/11$  or  $f/16$  will be found quite satisfactory. Here, again, there are several lenses of old types which may occasionally be bought secondhand, and which will give excellent results for copying. The Dallmeyer triplet, for example, which works at a maximum aperture of  $f/10$ , and the Ross Concentric, which gives a flat field free from astigmatism at its open aperture of  $f/16$ , and which covers well at a wide angle with very even illumination; both make admirable copying objectives. Where there is great variety in the size of the originals or the size of the negatives to be made, or both, it may be found well to have two lenses available—a short focus lens where enlarged negatives are required from small originals, and a lens of greater focal length and good covering power for copying larger originals the same size.

Turning now to the adjustments: where a print of good size is to be copied smaller, little difficulty occurs. It is when a print of, say, locket size has to be enlarged considerably that the usual trial and error method of getting the image the correct size on the ground glass proves tedious. By making a very simple calculation the relative positions

of original, lens, and plate may be readily determined for any variation in size between the original and negative. The data for this simple calculation are the degree of enlargement and the focal length of the lens. Suppose a 5 x 4 print has to be copied to 15 x 12. The degree of enlargement is 3 diameters, 15 being 3 times 5, and 12 being 3 times 4. Suppose also that a lens of 6 inches focal length is being used. The rule is:—Add 1 to the times of enlargement, and multiply this by the focus of the lens in inches. The product will be the distance from the lens to the plate. Then divide this distance by the times of enlargement, and the second distance, that from the lens to the original, is obtained. In the instance given,  $1 + 3 = 4$ . Then  $4 \times 6 = 24$ . The distance from lens to plate will be 24 inches. Then  $24 \div 3$  (the times of enlargement) = 8 inches, which will be the distance from lens to original. Thus, by raising out the copying camera to an extension of 24 inches and placing the lens 8 inches from the print, little or no further adjustment will be needed except fine focussing. The rule applies equally to reductions in size, the distance being reversed.

In the case of lenses of symmetrical or approximate symmetrical construction the measurements may be made to the diaphragm of the lens. Such lenses are the rectilinears or aplanats, and the majority of the anastigmat doublets. In two well-known cases, the Cooke and the Aldis anastigmats, the measurements must not be made from the stop, the focus of the lens being measured from point in front of the lens. It is easy, however, to make allowance for this. With a lens of 6, 7, or 8 inches focus about an inch may be subtracted from the "lens to plate" distance and added to the "lens to original" distance.

Most modern lenses have their focal length engraved on the mount, but it is quite a simple matter to ascertain the focal length if the copying or other camera available possess sufficient extension. Two slips of paper may be cut exactly the same length. One of these is placed on the copy board and the camera distance and extension adjusted until the image on the screen is exactly the same size, the second slip being used as a measure. The lens is now screwed out of its flange and the distance between the paper on the copy board and the ground glass is accurately measured. This distance divided by four gives the focal length of the lens.

## DEVELOPMENT WITHOUT ROCKING.

DR. NEUHAUSS, the Technical Editor of the "Photographische Rundschau," in which the above article appears, says: "With his manuscript the author sent me a large number of negatives, some of which were developed by the old hand method, and some by the new. Most of them were very difficult subjects, for instance, taken against a bright window. The results by the author's new method are absolutely astounding; exposures, which by the old hand development were quite useless, gave with the new method negatives of exquisite fineness. We can only strongly recommend our readers to try this method."

Everybody knows how wearisome the development of plates by hand\* is, especially when a number have to be developed and slow developers are used. Stand development in grooved troughs is some help, but both methods have their disadvantages.

At the suggestion of a well-known worker, who did not follow the matter any further, I have arrived at the following method of development, which has proved perfectly satisfactory and gives very beautiful negatives even with some over-exposure, and it has also the advantage of cheapness. To understand this method some preliminary remarks are requisite.

### A Theory of Development.

When a plate is exposed, where the light falls there is formed silver sub-bromide; after exposure we have then silver bromide and sub-bromide in the film. During development the sub-bromide is reduced to metallic silver and bromine is set free. The latter com-

bines with the alkali in the developer to form alkaline bromide. In hand development the bromide formed is equally distributed throughout the developer. The presence of bromide in the developer checks the reduction of the silver sub-bromide to metallic silver. For this reason bromide is added to the developer in the cases of over-exposure. This restraining action is exercised in the shadows as well as the highlights, for the bromide is by the rocking of the dish evenly distributed throughout the whole of the developer. In hand development, therefore, the retardation of the silver reduction is equally distributed over the whole of the plate, and a partial action on the reduction of the silver in places where it is desirable is unattainable. Stand development shows the same fault, for the bromide formed sinks in consequence of its specific gravity to the bottom.

There is therefore nothing left but to place the plate film up in an absolutely levelled dish, and after pouring on a weak developer leave it undisturbed. With this method of development the bromine set free in the most exposed parts of the plate sinks down as sodium or potassium bromide and remains there, as the plate is not rock-

\* The author obviously means by the term "hand development" normal development and rocking of the dish by hand. EDS. B.J.

development is finished, and thus acts as a special restrainer at these places, especially as the bromine "in statu nascendi" appears to act more energetically than when it is as added drop by drop as bromide to the developer.

#### Localized Restraint.

The restraint of the development is regulated by this process in the most correct way, for in the shadows, where little bromine is set free, there is no or very little restraining action. In the high-lights, on the other hand, there is strong restraining action. The result is, that not only is the negative more even than when hand-development is used, but also over-exposure or halation are almost completely compensated for. For landscapes with deep shadows and bright high-lights, this method of development is specially to be recommended. The most practical solution for this method of development I have found in Von. Hübl's glycin stand developer diluted 1:40.

#### Quiescent Development for Half-an-Hour.

The method of working is as follows:—A box with a light-tight cover should be obtained and the inside painted black. In this should be placed the developing dish, and in this the well-dusted plate,

which is quickly covered with the well-diluted developer. Any air bubbles are then removed and the box closed. The cover must cover all sides and not stick, so that there shall be no shaking of the plate. The box with the plate must be absolutely level. The dark-room may now be left, and after about half-an-hour the cover may be very carefully lifted and the plate examined without touching it, so as not to disturb the developer. It is extremely easy, especially if a porcelain dish be used to judge from time to time as to the progress of development. If some plates are developed they should be lifted out as carefully as possible so as not to disturb the developer over the others. The finished plates can be fixed as usual and the cover replaced, and the others left till finished. Development in no case lasts longer than  $1\frac{1}{2}$  to 2 hours.

If the dish is not absolutely level the bromide formed moves slowly in a wave to the side, and not only is the effect lost, but the bromide acts in the wrong places and wavy lines are caused, corresponding to the movement of the salts.

I hope that the above notes will lead to further experiments, and shall be glad to think that others will obtain equally happy results

RUDOLF WALTER.

## REMBRANDT: A GREAT NAME AND A CATCHWORD.

I have often wondered whether the young lady who calls at a photographer's on her way home from the factory in south-east London, and asks for three cabinet Rembrandts, really knows what she is asking for. It would be interesting to hear how she would answer if she were confronted with the query "How do you know, Miss, that the charming likeness of yourself there is not a Holbein, a Moroni, or a Sassoferrato for the matter of that?"

#### What are Rembrandts?

It is not to be thought that Rembrandt himself would have objected to the use of his name as a trade label. He was a man of the world. But with a "Rembrandt" photograph before him he would no doubt have failed to see why his name had been pitched upon for the honour. What he delighted to exercise himself with was the play of reflected light that enriched, clarified, and yet did not rob the depth and breadth of large and sweeping shadows. He found joy in the concentration of light to make brilliant accents upon faces and passages of costume. In comparison with these sparkling passages, the shadows were quiet and even; empty they never were. This marked comparison between light and shade makes a forcible impression upon those who read as they run, but do not stop to study and enjoy. It is this very obvious effect only which has come to spell Rembrandt to those who know the master's works from a cursory glance at a few indifferent reproductions alone. Photographers have availed themselves of the undoubted advantages in the matter of simplicity and a certain kind of strength that comes of this treatment, and the result is that its characteristics have been crystallised into a formula, according to which prints are made and dubbed "Rembrandts."

If every photographer had paid a visit to the Royal Academy in the winter of 1899, and there seen the unique and magnificent collection of Rembrandt's paintings, he would have seen that the work of this giant meant more than a trick of chiaroscuro. They may still come to the fulness of this knowledge by viewing those in the National Gallery; or they may discover an interesting collection of reproductions at the Fine Art Society's Galleries in Bond Street. This exhibition has been formed to commemorate the tercentenary of Rembrandt's birth (and incidentally to sell a few prints if possible). Here the photogravures are all more satisfactory than the etched copies, because the harsh and texturous quality of the latter do not give the suave and flexible handling of the originals as do the photographic versions, which, further, preserve better the details of form and

modelling that go to make up the wonderful personalities of the sitters, and the elusive subtleties of their expressions.

#### The Glory of Technique.

In three hundred years no star has arisen to pale the glory of Rembrandt. In his line he is the true prince of painters. Reproductions of him are but mere shadows. One must see the originals to feel anything like his full force. The glow of his mellow and harmonious colour, the soft brilliance of his flesh tones, and the lambent sheen upon armour, jewellery, and embroidered garments—these qualities are not even suggested in monochrome copies. And it is a lost art to-day. We may paint more realistically, more exactly, but we cannot get the poetry of these commonplace phenomena; and if we could we should fail to combine it with that masculine breadth of treatment, that mighty conception and laying out of a subject that makes these poetically-rendered commonplaces mere subsidiary matters in the main process. Our painters to-day have to give all that kind of thing the go-by when they try for the simple and large impression, and, therefore, works of such a class do not move "the man in the street." They are an acquired taste. It was not so in Rembrandt's case. The honest and unsophisticated old burghers and their wives were quite equal to an appreciation of the master's works, and the most eclectic of our art critics to-day find them objects of adoration too. Such a wide appeal is only possible to the highest form of genius.

But in these days we do not attempt to paint like the old masters although we admire them. We have not improved upon them; we have differed from them, and shall grow more and more unlike them. Painters have always had Rembrandt's principles in mind, but it would be a deliberate affectation to place a sitter beneath a tiny window in a dark room for the purpose of imitating the style of the Amsterdam master. Painters leave that sort of sincere flattery to the photographers, whose paraphernalia lends itself exceptionally well to that sort of thing, and whose results justify their means both artistically and commercially. The professional photographer has to work in monochrome, and nobody can teach him so well as Rembrandt how to get the best effect from mere light and dark.

The life of this great master was made up of light and dark. It had its period of joyous opulence, colour, sweetness, and tenderness, and it was not without its passages of gloom—real shadows from his brighter days, wherein, however, his art always maintained a power to move the spectator.

During his closing years he had confined his efforts to portraits

of himself. Probably no artist ever represented his own face so often. Throughout his life it was his practice, and many works that bear fancy titles or sham names are the master himself masquerading in false beard or wig, or in the fanciful oriental costumes of which he probably had a large collection. His wife Saskia likewise figures over and over again in various characters; and his father, mother, and sisters are all handed down to posterity in the same way.

#### Rembrandt's Art.

It was not in portraiture alone that Rembrandt made his fame. Subjects from Holy Writ often employed him, landscape was carried to sublime heights by his achievements, his etchings abound by hundreds and are still transcendent, and countless figure and character studies exist in water-colour.

He was a true Dutchman in whom the grace and sweetness of the classical Italians found no favour. His art was an outlook on life. The facts of nature and their meaning to men constituted his material, not the sophistications of the aesthetics in the south. All his portraits have something to say about themselves. They are alive, and all but speak. Perhaps his greatest marvel in this respect is "The Shipbuilder and his Wife." The wife enters with a letter, and without letting go the handle of the door, offers the letter to the shipbuilder who turns from his accounts to take it. One positively waits during the momentary pause in their movements as though to see what will happen next. The sense of life in the figures is astounding, and their healthy, comely faces are warm flesh and palpitating blood. The whole thing is given solidly and convincingly—a startling impression without "impressionism." I shall never forget the effect upon my mind when I saw this stupendous work seven years ago. I give the example as typical.

There is no high faultin' about Rembrandt. He laughs at modern "fakes" and tricks, getting the supremest effects by simple and unaffected methods. As a landscape painter he lives in my memory by his "Mill," amongst his oil pictures, and by his marvellous etchings, wherein the needle point has performed miracles of drawing in distances and tree forms. The popular notion that all Rembrandt's works are black things with high lights is a delusion. He very commonly plays with the magic of light and shade in that way of brilliant contrast, but it by no means represents the whole range of his art.

#### The Real Rembrandt Lighting.

A more particular characteristic is the gradual fading away of light from a chief bright spot. Rembrandt never makes the mistake of having more than one culmination of brightness, and it always occurs at the point of greatest interest of subject. That is to say, in the portraits the strongest illumination is upon the cheek and nose, and almost invariably falls from the left side. In the subject pictures the light is focussed, often in a stagey way (whisper it not in Gath), upon the principal figures. The mastery of Rembrandt comes in at the supreme management of this strong light and its surroundings. In a few cases there may be a powerful contrast of the bright accent with the

deepest shade, but even where this occurs there is also a massing of less brilliant passages and points, and the further the distance from the principal accent, the duller becomes the subsidiary ones, until they melt into positive darkness. The effect may be likened more to that of a Milky Way than of a bright star in dark sky.

Rembrandt uses the shape and disposition of this waxing and waning passage of light as his chief material in composition. In those lofty and mysterious church interiors, where the subject is usually a biblical one, the lighting often takes a fine crescent-like sweep, fanning out at one of its ends into gloom. There is always perfect and logical gradation carried over the figures. One has only first to admit as a postulate that the bright illumination can fall as it does from some unseen source, and after that, all is perfectly naturalistic and the effect irresistible. The gradation is slow, of course, along the length of the light passage, and rapid across its width at the edges. The actual culmination may be forced by the dark accent of a figure standing before the bright group, and out of range of the illuminating beams. But it is not upon this contrast that the master relies for the brilliance of his principal accents; it is upon the gradation and massing. Any one may test for themselves how a number of light spots, gradating from a chief one, even if they be all within a range of greys, give a much more convincing effect of actual shining light than a mere bright and abrupt spot, even though it be white upon black.

The same principle is adopted in his portraits. The light dwindles away over the shoulders and background, here and there arrested upon embroidery, silver or gold lace, armour, or what not. It strikes everything cleanly and sharply, without in the least approaching to fuzziness, but always in a lessening strength as it is removed from the chief accent.

That it is which seems to me the important lesson to be learned in the making of fine portraits. There is no occasion for smeary, woolly murkiness so long as the light is allowed to get less bright as it spreads from the face. It may then be allowed to have all its own proper scheme of light and shade in folds, dress ornaments, and so on.

Another point in which Rembrandt's example should be respected is in the matter of backgrounds. His are never a meaningless darkness. They can always be supposed to be something solid upon which light might fall. Light does usually fall upon them in a soft broadly luminous glow, always well and fully gradated. His heads do not sink into them, but always appear well detached from them. I cannot say as much for the majority of those photographic backgrounds that bear the proud evidences of the photographer's "control" in the shape of streaks, blot, and other aggressions which come forward in front of the head. The shadowy sides of Rembrandt's heads can usually be traced in a fine firm contour throughout the darkest background, and as a rule they are gently relieved by a slight advantage in depth of tone over the background at that part.

F. C. TILNEY.

PHOTOGRAPHY, as many of our readers know, is one of the many interests of the Duke of Newcastle. The Duke, according to "Modern Society," built a studio at a little distance from the house, where he can follow his favourite art undisturbed. Some short time since he fancied that if the upper story of this building had another aspect the light would fall more suitably. So this upper part was turned completely round by a process similar to that adopted in America for the removal of buildings; and, to the Duke's immense pride, his own workmen accomplished the feat under his own personal supervision.

A DEALER'S Suggestion to Advertisers.—In the "Chemist and Druggist" a suggestion is made to the drug advertisers which may be also of some interest to those appealing chiefly to the photo-

graphic dealers. The writer says:—"Might I respectfully suggest that advertisers should occasionally insert an advertisement appealing to the general public and capable of being cut out and pasted on a card-mount? Trade terms, etc., could be printed at foot, and cut away when displayed on counter or in window. I think many would appreciate this, especially those whose time is very limited. The 'cutting out' has already been suggested in your columns, and if a chemist is willing to do this why should not the wholesaler assist him?"

THE Birmingham Photographic Company, Limited, Criterion Works Stechford, advise us that from now until Christmas they are placing in all their packets of postcards, P.O.P., Celerio, gaslight, and bromide, a Christmas greeting border negative, without extra charge.

## ON WORKING "ART VELOX" (GASLIGHT) PAPER.

The beauty of a print in "art Velox" will come as a surprise to those who are unacquainted with the process. The delicacy of the pearly lights and the brilliance and transparency of the shadows are only equalled by a fine carbon print from a negative exactly adapted to that process. But a fine print can be obtained in "art Velox" from a negative hopelessly too thin and weak for any other process; and by using the "Soft" grade paper an equally fine print can be made from a negative strong enough to give a good print in carbon, but with a hundredth part of the work involved in that process. The surface has a slight and delicate gloss, similar to a carbon print by double transfer from flexible temporary support. Prints can be made on the paper by the method usually adopted for the other grades of the paper, a method too well known to need description. But the professional photographer will not find it best to adopt the method already in use for bromide printing, and develop the prints in dishes by yellow light. It may at once be pointed out that a dark-room light which is safe for plates is of no use for Velox printing; a bright yellow light, and plenty of it, must be used, or it will be impossible to secure uniform prints. Velox paper is much slower than ordinary bromide, and will bear a larger amount of light in development, and will need a more powerful light for exposing. An incandescent gas burner will be found most efficient for ordinary negatives, but for those of large size, or great density, daylight may be used with advantage, of course making a test exposure on a small piece of paper. For an average negative, such as will give a good P.O.P. print, the printing-frame should be about six to nine inches from the light, and an exposure of twenty seconds should be sufficient. If the negative is yellow with pyro stain the exposure will be longer, but if the plate has been developed with metol, hydroquinone, ortol, etc., the exposure will be shorter, perhaps ten or even five seconds.

## The Raison d'être of this Article.

But when the photographer comes to development he will find that he must abandon most of his ideas formed from experience in printing with ordinary bromide paper. For instance, he will think that if he wishes to secure a soft, delicate print he must use a dilute developer, but with "art Velox" to get a soft print he must use a concentrated developer. To get a brilliant print he will want to use a decidedly concentrated developer, but with "art Velox," for contrast, he must dilute the developer. For thin negatives he would give a short exposure and a strong (that is, a concentrated) developer; for "art Velox" he must lengthen the exposure and water the developer. This rule of contrary seems to run through all the process, for if a print develops too dark and heavy, especially in the shadows, he will think the exposure has been too short, but he will find that it has been too long, and that a shorter exposure will give a soft, delicate print.

An "art Velox" print also acts in quite a different way during development from what he will expect. A properly exposed print when plunged into the developer usually goes grey all over, at once, and the novice thinks it is hopelessly fogged, but almost before that feeling has passed through his mind, he will see the delicate lights appearing out of the grey fog, and the deep shadows growing strong, and in a few seconds a fine print will appear, and development be complete in about thirty seconds. If the image appears slowly, as in a bromide print, he may as well throw that piece of paper away at once, for it will be useless, unless the negative was excessively thin and the developer extremely weak. But excessive dilution of the developer is not recommended, as it is liable to cause curious white patches and streaks in the image which do not develop at all; this is often aggravated by storing the paper in a damp place. The moral,

therefore, is, have negatives of fair density, so that there will be no necessity for great dilution of developer.

## Modification of Developer.

The developer recommended by the makers of the paper contains sodium carbonate as the accelerator, and a larger proportion of hydroquinone than of metol. This formula is excellent for delicate negatives, but when a stronger one, such as would print well in carbon, is used, the sodium may be replaced by potassium carbonate, and for still stronger negatives the proportion of metol to hydroquinone may be reversed, or metol only may be used with potassium carbonate. For very hard negatives the quantity of potassium may be increased to as much as one part of normal metol solution to six parts of potassium carbonate, instead of one; and this may be done without altering the colour of the finished print. But development will need to be slightly prolonged to avoid flat, weak prints, lacking in strength in the shadows. On the other hand, dilution of developer, or the addition of bromide, leads to brownish prints, and even to dirty greens; such prints, if subsequently toned, will become very yellow in colour, instead of a rich brown sepia. The amount of bromide should be as low as possible, too little producing grey whites and losing detail of the more delicate tones, while too much gives heavy shadows and greenish-brown prints. But it will be seen that endless changes can be rung in mixing developers, if a normal Velox developer is made up (but with the sodium carbonate in a separate solution), and a bottle of metol developer, and one of a solution of potassium carbonate, 3 oz. to 20 oz. of water.

If a delicate negative has to be printed the normal Velox developer should be used; if this gives too soft a print, a little water may be added to the developer, and a little longer exposure given. For a stronger negative potassium may be substituted for sodium carbonate; if this gives too soft a print a little water may be added. For a still stronger negative the amount of potassium may be increased, and also some metol solution may be added. For still stronger negatives metol and potassium, with a very small quantity of bromide, may be used, and the amount of potassium carbonate increased for still greater density of negative.

## Exposure in Relation to Developer.

The exposure of the paper is a very important matter, for when using the normal developer of hydroquinone, metol, and sodium carbonate the exposures will need to be fairly long in order to secure brilliant prints. But when potassium carbonate is substituted for sodium, for a denser negative, the exposure should be decreased, not increased; and when metol only, with potassium, is used the exposure should be still further decreased. And as the quantity of potassium is increased the exposure should be decreased. But too short an exposure will need longer development, and this may produce yellow high lights; a diminution in the amount of acetic acid in the fixing bath is liable to produce the same defect, unless the development has been very short indeed.

## Fixing-Bath Causes of Failure.

The fixing bath recommended by the makers of the paper must always be used, otherwise endless trouble will ensue such as yellow prints, blisters, black streaks, etc. When using ordinary bromide paper great care must be exercised to avoid handling the paper while in the developer with fingers contaminated with even a very small trace of hypo solution, or black streaks and yellowish-brown stains are inevitable; and if the prints are to be after-toned there will be black marks and streaks which remain obstinately colder in colour. Such marks are caused by developer and hypo being allowed to remain on the print to

gether. With "art Velox" precautions against hypo stains must be even more stringent. It is best when developing to use the right hand only for handling the print while in the developing dish; and the left should be reserved for moving the print about, as soon as it touches the fixing solution, so that the whole surface is exposed, at once, to the action of the hypo. The left hand should never touch a wet print until it arrives at the fixing dish; and the right hand should never touch a print after it has arrived at the fixing dish, without very careful washing; rinsing will not do. But when handling the dry paper, both before and after printing, the same care is not so essential, provided the fingers are dry, although dirty fingers do not improve the paper at any stage.

There is scarcely any perceptible change in the appearance of the paper when dry; there is none of that flattening and blocking of the deep shadows experienced with bromide prints; the delicate tones may dry a very, very little darker, but that is all. The deep transparent shadows do not alter.

The paper support is thinner than with bromide, and therefore washes more quickly, especially in rotary washing tanks, as the prints move freely round instead of lying in a mass at the bottom.

Many who have tried Velox paper have given it up on account of getting harsh prints with high lights stained yellow, and these failures have been generally caused by treating it as they would ordinary bromide paper. Good prints cannot be made unless the instructions issued with the paper are carefully followed, especially those as to the length of time in the developing solution, and the acidity of the fixing bath. Yellow prints are caused by several things, either by too short an exposure, which involves too long in the developer; by too small a quantity of acetic acid in the fixing bath; or too long fixing in an old bath in which the acid has been neutralised by the alkali of the developer, carried into it by the prints. Prints should be quickly rinsed before fixing.

Continuing development longer than thirty seconds is a prolific cause of yellow stains. But a print which is otherwise good but with slight yellow stains will "tone" to a fine sepia colour, and the stains will not show, so that a batch of yellow prints may be saved by converting them into sepia ones.

#### Sulphide Toning.

The simplest toning method is the one so well known, now, which converts the black metallic silver into silver sulphide. The prints are first bleached with a solution which changes the silver of the black print into the yellow bromide or iodide of silver, and then a solution of sodium sulphide is applied, which converts the yellow bromide or iodide into silver sulphide, of a rich brown colour, and believed to be a very stable salt. The

prints to be toned must be thoroughly washed, or the delicate half-tones of the picture will be reduced in the process of bleaching, and they should be well hardened with alum or formalin, and allowed to dry. If this precaution of hardening is omitted there will be a great risk of blisters appearing in the process of washing out the sodium sulphide, which has a powerful softening action on the gelatine.

The simplest method of toning is to bleach the prints in potassium ferricyanide (red prussiate of potash), 400 grains, potassium bromide 600 grains, water 10 ounces. The black image is converted in a few minutes into a yellow bromide; the prints must then be washed for at least five minutes in frequent changes of water until the yellow ferricyanide has been removed from the surface of the paper; they are then "toned" in a very dilute solution of sodium sulphide until the whole of the silver bromide has been converted into silver sulphide, which should be of a rich sepia colour. A few drops of a saturated solution of sodium sulphide to ten ounces of water is quite strong enough to produce the change, but the prints should remain in the solution for some minutes after the conversion is apparently complete, to insure that the whole of the bromide is converted into sulphide. The sodium sulphide must now be washed out, and it is at this stage that blisters may appear. If the water supply comes from sandstone or chalk district, and is therefore "hard," there will be little danger of blisters; but if it is rain water or other "soft" water, such as that supplied at Liverpool, Glasgow, Manchester, and Birmingham, blisters are inevitable, unless precautions are taken. It is advisable to have only a few prints in the sulphide solution at one time, and as each one is finished it should be removed to a diluted solution of chrome alum, without washing; in five minutes it may be transferred to the washing tank, a prolonged washing is not necessary. Another method may be adopted which is equally efficient, unless the water is very soft indeed, and that is to immerse the prints as they are toned in methylated spirit, which need not be fresh, but that which has been used for drying plates or prints. Potash alum may be substituted for chrome alum, but it is liable to produce a white deposit on the prints, which must be cleaned when dry with a tuft of cotton wool moistened with methylated spirit.

Velox prints may be dried face downwards on cheese cloth, to prevent any slight tendency to curling; the film is so hardened by the fixing bath that they will not stick. In extremely hot dry weather prints treated with chrome alum will be rather curly and unmanageable, but this may be prevented by soaking for a few minutes in water, to which a small quantity of glycerine has been added, before laying them out to dry.

HAROLD BAKER.

## FOCUSSING SCALES BY A GRAPHIC METHOD OF DETERMINING THE CONJUGATE FOCI.

No one will deny that inaccurate focussing scales are worse than useless, which suggests the necessity of testing our scales, but only those who have attempted to obtain tests by actual trial with the camera, would realise the trouble it takes to get accurate results. Calculating and plotting is reliable, though somewhat tedious, and requires checking, besides being beyond the scope of many photographers; but, by the following graphic method—which is mathematically correct—any one with a sharp hard pencil and a scale, or divided rule, should be able to draw their own focussing scales with a considerable degree of accuracy.

From a straight line A B let fall a perpendicular C D three inches in length. From C mark C1 equal to one fourth of the actual focal length of the lens for which the focussing scale is required. Then with any regular scale (a quarter inch is con-

venient) from D and parallel to A B set off distances 4, 5, from which draw lines to C.

From 1 parallel to A B draw 1F, cutting lines C5 and C4, 1F, and E, which is the initial point. And from F draw F1 parallel to A B parallel to C D. From F1—the measuring point—set off on line A B from the scale, the distances or stations, which the focussing scale is required to represent—usually 5, 7, 10, etc. feet (or for yards multiples of three) and draw lines from these to the initial point E. Then the intersections of these lines with the perpendicular C D indicate in terms of the focussing scale the corresponding distances of the stations from the initial point 1.

If after setting out a few stations on line A B we find that they are likely to extend beyond the limit of our paper, the

we may proceed with a smaller scale, say, 1-16th of an inch, and as this is one fourth of the scale previously used, set off from C the distance C G, equalling—by the scale—the focal length of the lens, and draw G H parallel to A B, and project its intersection with line C5 up to A B—forming the new measuring point F11—and with C4 down to line E1 to form the new initial point E1 from which operations with the new scale may be continued as before. If scales for longer focal lengths

The larger linear scales tend towards greater accuracy in the delineation, on account of the angles of intersection being more obtuse. The diagram is necessarily somewhat compressed laterally in order to save space, although one scale—an eighth—is ample for the shorter focal lengths. Yet in the same diagram we may use as many different scales as convenient, provided that the lines from the new initial points, and the distances from the corresponding measuring points, are to the same scale, and if

This diagram shows a focussing Scale for a lens of 9 inches equivalent focus.

are desired the lines C and D, and 4 and 5 may be extended, or the distances—of the measuring and initial points—from the extended D C, calculated and plotted; which would give respectively for the lenses of 9 and 19 inches focus, 3 and 3 $\frac{3}{4}$ , and 6 1-3rd and 7 11-12th divisions of the quarter inch scale thus:—

2 in. lens.	Initial point	$\left\{ \begin{array}{l} \frac{4}{12} \times \frac{9}{1} = 3 \div 4 = \frac{3}{4} \text{ of an inch.} \end{array} \right.$
	Measuring point	$\left\{ \begin{array}{l} \frac{5}{12} \times \frac{9}{1} = 3\frac{3}{4} \div 4 = 1\frac{1}{4} \text{ " " } \end{array} \right.$
19 in. lens.	Initial point	$\left\{ \begin{array}{l} \frac{4}{12} \times \frac{19}{1} = \frac{6\frac{1}{2}}{4} = 1\frac{7}{8} \text{ inches.} \end{array} \right.$
	Measuring point	$\left\{ \begin{array}{l} \frac{5}{12} \times \frac{19}{1} = 7\frac{1}{2} \div 4 = 1\frac{7}{8} \text{ " " } \end{array} \right.$

any lines radiated from the initial points to their respective stations, happen to have been duplicated, their intersections will be in the same point on line C D which will prove the skill of the delineator—or otherwise—and the actual linear dimensions in inches—from the infinity mark to the figure marks in the focussing scale—plus the focal length of the lens, are the lesser conjugates full size, to their complementary distances on A B, or the greater conjugates by linear scale. This graphic method would, I believe, prove useful for many purposes where the conjugate foci are required.

JULIUS H. HOMAN.

We refer to Mr. Homan's article at the foot of a letter on another page.—Eds. B. J. P.

## LETTER TO A MIDDLE-CLASS PROFESSIONAL.

DEAR J.—I believe that last year I wrote you immediately before Christmas impressing upon you the opportunity there is at that season to do rather more than the ordinary amount of business. I am glad you remonstrated with me regarding the somewhat tardy arrival of the advice. This time you see I have taken your remarks to the eleventh hour to heart. Indeed, if any work at all is to be done in Christmas lines' preparations, it should be made well in advance. The public are so extremely lax and slow that unless the proximity of the festive season is forced upon them everything is left until the last minute, as you know, from that rush order of yours received the day before Christmas Eve. Whatever you do you are bound to have one or two orders at the last minute, so if you are wise you will get all orders out as quickly as possible, so that the dis-

location caused by the last one or two received will not affect the earlier ones to any great extent. You say that you are doing Christmas midgets again, and, of course, I expected it, the small photograph, mounted on a Christmas card, being the sum total of the efforts made by professionals to get a share of the profits that go mostly to the fancy goods and silversmith men. With a little effort some of your cabinet pictures ought to go. Just get out an advertisement for that local paper and dwell on the suitability of photographs for presents—not greeting cards, but presents. You don't think much of the paper as a means of publicity, I believe, that is, because you have struck off some humdrum ordinary business about Mr. J., photographer, doing enlargements, miniatures, and copies, and left the newspaper man to set it anyway. This time

keep to the one point—presents and photography—and show the type and ruling you want. That last advert. of yours was all right, but those abominable ornaments spoilt it. This time make sure that there are no printer's ornaments about your matter, and only a plain rule round. Of course, if you feel rather flush, and don't mind spending a little money that will bring its return, not immediately, but in the future, get out a really smart neat leaflet, on good quality writing paper, and mail it under a penny stamp. The extra orders may not pay for it, but I expect to hear that you are not quite so slack this spring.

That last specimen you sent me in the folder was excellent. Why not have a Christmas greeting printed on the outside this time? The print and mount will not be affected in any way, but the result will be seasonable enough. Of course, you did not do much with Christmas work last year. When I slipped over to see you I noticed that your cases were as usual. You cannot possibly expect to do the business if you do not exhibit your goods. I daresay that most people had no idea you were making portraits specially for gifts. The old saying, "Out of sight is out of mind," is applicable here. A good show of seasonable work will create a desire in the minds of prospective sitters who would never have thought of photographs had they not been unconsciously suggested. For those smart clients of yours you should get a sample book of cards, upon which their name and address can be printed. When you are thinking of knocking off about four o'clock, think what an expensive time you are going to have, then get some good notepaper and drop a line to your old customers, saying what a nice Christmas card you could make from their last sitting, and offer to send samples on approval. I know you are not very busy now, so don't you think you could look out the last sitting and do a print of it, mount it up suitably, and forward that with the letter? If you don't get an order for more you will nearly always sell the one for a trifle more than its cost, and the cost of paper and postage.

It is not often we get asked for calendars, simply because a photographic calendar is rather original. If you think you could sell a few, and your receptionist is rather smart, get some 1907 pads from the local stationer, and fix them with adhesive or paper

fasteners on the bottom margin of some of your big mounts, then punch two holes in the top and tie a loop with silk ribbon. At no expense whatever, that, dear J., will touch you; you obtain something fresh and novel. Be careful about the pads, though. The tinker, tailor, etc., usually manage to give their clients a calendar at this season; the said calendar usually finds the dustbin, together with the orange peel and turkey bones, but that is because the aristocratic name and trade of Mr. Tinker or Tailor is somewhat prominent. Now, no business is more suitable or lends itself better than ours to the production of an artistic date recorder, so why not work on the hint?

If properly done, it should be equally acceptable as the ones purchased from the bookseller, and be a standing advertisement all the year round. A really good print should be selected from your specimens and used for the illustration. Mount it on a mount of suitable tint and size. Bromide prints are the best perhaps, so a grey mount should be used. Be sure that the plate mark is well above the centre, leaving room for the date pad. This latter should have a cover, with the year on it, of exactly same shade as mount. The printer you get your sundries from is sure to have some type set up from which he will print you anything fairly cheap. I should advise, however, that the name and address is exactly the same as on your ordinary mounts. If you feel like doing the thing really well, the dates could be scattered over the mount each month in a frame to itself. Probably the printer is doing some for himself, and will put your mounts through the machine for a small consideration.

Get a shade of good silk ribbon that goes agreeably with the mount, and thread it through two holes, punched about three inches apart, and at the top of calendar. Tie with a good big bow. It will not take very long to get a few hundreds off, and the wife, you know, could help with these bows. I believe from what you said that a promise of millinery was a great aid to the smooth running of affairs. I hope the results from the calendars will make it more than a promise this time, though.

Well, it's about time I looked after my own business, but do, do, clean that skylight of yours.—Yours,

PROVINCIAL PRO.

## HOW DEVELOPMENT OCCURS.

(Abstract of Lecture by Mr. C. E. Kenneth Mees, B.Sc., at the Croydon Camera Club.)

"How Development Occurs, *Simply and Popularly Explained*" (the italics are own own) was the precise title of Mr. Mees' lecture appearing in the club's fixture list for the 31st of last month, and given by him on that date. A large number of members assembled and listened with close attention to a really clear, if not altogether elementary dissertation on a difficult subject, the salient features of which, with the subsequent discussion, was epitomised. It is, however, only fair to Mr. Mees to mention that he denied being the originator of the italicised words above, and it was therefore not unnaturally assumed that the club's hon. secretary had been indulging in a slightly ironical vein of humour. This was, however, not admitted, and the matter remained wrapped in mystery.

Mr. Mees said, that in discussing the method by which development occurs, there are two things which must be considered. 1. The whole reaction, involving not only the chemical reaction of the reducer with the silver bromide, but also the getting of the developer into the film, and of the waste products out again. 2. The chemical reaction itself. They were aware that both these branches had been studied by a member of their club (Mr. S. E. Sheppard), with whom he (the speaker) had done much of his work, and it was chiefly the result of those studies which he proposed to explain.

### A Graphic Account of Development by Ions.

To take the chemical action first. Reaction involved solution, and solution involved ionisation. So that the chemical change must be regarded as taking place between ions, or, in other words, between electrically charged atoms. A developer, in fact, consisted of an ion, which could lose a negative charge, to neutralise the positive charge of an ion of silver. This rapidly produced a supersaturation of

metallic silver in solution, which stopped further solution of silver bromide, and consequently further reaction, unless a nucleus presented itself for precipitation. This nucleus might be any foreign matter, in which case fog was formed; or it might be the latent image. Thus, from the point of view of development, the latent image consisted of nuclei for the deposition of supersaturated silver. Once a particle had commenced deposition from any cause, then that particle would in time be wholly developed, but was apparently not appreciably reinforced from neighbouring particles. The film itself might be regarded as a network of closed cells, with corridors in between, and the particles of silver bromide locked firmly in the cells. The developer could then pass rapidly and easily through the corridors, but only slowly and with difficulty, through the cell walls.

The velocity of development depended chiefly upon the rate of access of the developer to the silver bromide particles, and of the clearing away of the developer products from the particles. Development began rapidly, and then fell off in speed, finally reaching a limit. Plates differed from each other, both in rate at commencement and in the limit attained. The paper was illustrated with experiments and lantern slides, and by the use of most ingenious atomic models, consisting of small lumps of "plasticine" of different colours, which adhered to the blackboard, and were fastened together with matches.

### Saline Persiflage.

Mr. E. A. Salt, said he had listened to Mr. Mees with great interest; he had, however, overlooked filtration as a disturbing factor under certain conditions. Let it be assumed, and the assumption

as reasonable as many, that the plus and minus electrically charged atoms actually partook in shape of their characteristic signs. Then, with a sufficiently fine filtrate, all the minus ions approaching would pass through the pores, thus, +, whilst the plus ions would inevitably jam, owing to their shape, and distillation would be effected. At this point the President (Mr. W. H. Smith), having grasped the full beauty of the theory as a suitable acknowledgment, promptly ruled the speaker out of order, amidst much laughter. He (Mr. Smith) inquired whether Mr. Mees could throw any light on the curious phenomena of reversal. Mr. Mees replied that practically nothing was known about it. Solarisation occurred with great over-exposure. This must be distinguished from reversal with normal exposure. Hypo in the developer, and many other things, would cause this.

### Factorial Development.

Mr. J. M. Sellers pointed out that the curves shown, illustrating varying rates of development, the differences of steepness of

gradation, did not appear to be in harmony with the principles laid down by Mr. Watkins. Mr. Mees did not agree. With factorial development, it was held that all the factors wanted were in the straight portion of the curve. If one plate were to take longer to develop than another, then the time of first appearance of the image would be delayed. Although all photographers should be grateful to Mr. Watkins, for introducing his system, yet it was not strictly accurate. As a matter of fact, the variation in Watkins' factors with different developers, might be regarded as due to small accidental variations. Organic developers gave small disturbing affects which produced these variations. Moreover, the X factor altered with various strengths. With rodinal, for instance, this was very roughly proportional. With a 1 in 8 solution, the X factor equals 8. With 1 in 40 the X factor equals 40, and so approximately. He was decidedly of opinion that the best plan to adopt, was to first ascertain the length of time necessary for correct development of any particular plate, at a given temperature or temperatures, and then to develop for that period. A vote of thanks to the lecturer was passed with the utmost heartiness.

## THE CAUSE OF THE FOGGING OF PLATES IN TROPICAL CLIMATES.

(A Paper in the "Chemical News.")

Some time ago, while in Upper Egypt, I had occasion to use a full-length camera with wooden double dark slides. I found the plates to be nearly always fogged, notwithstanding the fact that the slides were perfectly light-tight and all the ordinary precautions of the dark room were taken.

The fogging sometimes showed itself as an opaque clouding all over the plate; sometimes the outline of the woodwork of the slide could be seen, and sometimes the grain of the wood was distinctly visible.

Shortly after I had made these observations, an eclipse of the sun occurred which was total at Assuan, and many scientific men went there to photograph it. On developing their plates, they found that many of them were rendered worthless or their value as a scientific record was greatly diminished by the same kind of fogging which I have described, and they were at a loss to explain it, although some suggested radio-activity. I have recently investigated this, and the result gives what appears to be the explanation.

### Artificial Tropical Climate.

I took a quarter-plate double dark slide and placed two special rapid plates in it. On the one plate I put a thin piece of tissue paper, in the centre of which I had cut out a star-shaped hole; on the other plate I put an ordinary glass microscopic slide. These objects were inside the slide, and in actual contact with the film. I then placed the double dark slide in a metal box and heated it up about 40 deg. C., which is the average temperature of Upper Egypt in the summer time. The slide was placed on a porcelain support in the metal box, which was heated by a lamp.

After heating for fifteen hours I developed the plates, and found them to be very strongly fogged, the film being quite opaque; but under the place where the thin tissue paper was, and also under the microscopic slide was, there was no fogging. In the centre of the tissue paper I had cut a star-hole and on the plate opposite to it was a star-shaped mark which was quite opaque.

I tried various other objects, and found that they acted in a similar manner.

### Emitted Vapour is the Cause of Fog

The fact that the agent which produced the fogging could not penetrate glass or transparent tissue paper shows that it cannot be due to ethereal vibrations at all of the nature of light. It is due to vapours which are occluded in the wood at ordinary temperatures, but which are exhaled when the wood is heated. These vapours, which may be peroxide of hydrogen or volatile organic compounds from the varnish, possess the chemical property of reducing the salts of silver which are contained in the film, so that on development the plate appears to have been exposed to the light.

I tried another experiment by fixing a piece of brass tubing in a hole cut in the slide and making the joint light-tight, a plate was then put in, and the whole heated to 40 deg. C. in the metal box as before.

The brass tube was connected to a water-pump, by which the vapours in the immediate vicinity of the tube were aspirated out. The fogging appeared to be less under the place where the tube was than on any other part of the plate.

### Addressed to Tourist Photographers.

The value of these experiments to the photographer going abroad is apparent. He should get a thin piece of glass or mica with which to cover the plate in the dark slide and protect it from the vapours, and fogging would be entirely prevented by this means.

If the dark slide was opened and heated for some days, there is little doubt but that the vapour which causes the fogging would be expelled, and it could then be used with confidence in the tropics.

The simplest method of preventing the fogging is to paste a piece of paper over the inside of the wooden sliding pieces which are pulled out when the plate is about to be exposed, which effectually prevents the vapour from diffusing out of the wood on to the photographic plate.

JOHN McDOWALL, F.C.S.

The City Sale and Exchange have added another to their three photographic supply houses. The new establishment, to be known as the Sloane Square branch, is situated at 26 and 28, King's Road, W. In addition to maintaining the trade on the lines of the other two houses, namely, the keeping of a universal stock of apparatus and materials and accepting used apparatus in part payment for new, the West-end branch will devote a special large department to professional supply. Accommodation is provided for back-rooms, furniture, and all studio accessories, and a large stock of cases and other requisites employed by professional photographers

will be kept. The new business will commence, under the management of Mr. W. Robbins, during the course of next week.

CRITERION P.O.P. Competition.—The Birmingham Photographic Company's Competition for the best print on Criterion P.O.P. or Estona self-toning papers, has resulted as follows:—1st Prize (two guineas), F. F. Johnson, 63, Harlesden Gardens, Harlesden, N.W. 2nd Prize (one guinea), A. E. Parry, 11, Westmoreland Road, Liscard, Cheshire. 3rd Prize (5s. 3d.), C. V. Taylor, 5, Craven Road, Rugby. 4th Prize (5s. 3d.), H. Sutcliffe, 5, Golden Street, Paternoster, near Manchester. (The third prize being divided.)

## ROYAL PHOTOGRAPHIC SOCIETY.

THE session of the Royal Photographic Society opened on Tuesday evening last by a reception and conversazione, the occasion serving to mark the occupation of the enlarged lecture-room which has resulted from the removal of the partition wall between the old lecture and council rooms. The alterations which have been in progress during the summer months has placed at the Society's disposal a room which can accommodate upwards of 200 people, all of whom can obtain a comfortable view of the lantern screen.

wall-covering to the meeting room. The lantern screen is painted permanently on the wall, the white space being covered by green-covered shutters, which allow of pictures being hung on it, and thus preserve the continuity of the walls when photographs are hung upon them.

A large company assembled on Tuesday evening and approved these new arrangements. Some, perhaps, were visiting the house of the Royal Photographic Society for the first time, and

The new lecture room at the House of the Royal Photographic Society, 66, Russell Square, London. The left-hand photograph shows the lantern screen, which is covered when not in use by shutters covered to match the walls.

In addition to providing this facility, advantage has been taken of the change to re-decorate the room, and to fit it more adequately for the house exhibitions which are regularly held at Russell Square. The walls are draped for a height of six feet above the

Ceiling of new lecture-room at Royal Photographic Society. Probably painted by Angelica Kaufmann about the year 1770.

dado with a green arras cloth, which, though of somewhat strong colour to our thinking, is infinitely superior to the previous red for exhibition purposes, and at the same time serves as a suitable

therefore be interested in hearing of its history. No. 66, Russell Square is part of what was originally Bolton House, built in 1799 by Lord Baltimore. In 1799 Lord Loughborough, the Lord Chancellor of the day, took a lease of the house until 1806, about which date the house was divided, and 66, Russell Square became known as such. At that time there were no buildings between the house and the present Guilford Street, for it was not until 1845 that buildings extended northward towards the present site of the House of Russell. Had the Royal Photographic Society had its home in Russell Square in Thackeray's days, its surroundings would have been exclusively the sombre and respectable one of City merchants and of those who wished for quiet in the centre of London. A motor omnibus has changed the character of the square completely, and the majority of its present residents, such as Mr. Geo. Grossmith and Miss Gertie Millar (Mrs. Lionel Monckton), doubtless put up with the scream of the traffic for the sake of being within a five-minute drive of the West End.

Members and friends on Tuesday were received by Lord Crawford (past-President), in the absence through continued indisposition of Major-General Waterhouse (President). Lord Crawford afterwards delivered a short address, in which he welcomed those present, and invited them to inspect the demonstrations and objects of interest. These, as already announced in our columns, included printing by the mercury-vapour lamp of Messrs. O. Sichel and Co., portraits by the mercury-vapour lamp by Messrs. A. W. Isenthal and Co. Kay; three-colour photography by Mr. H. W. Lewis, of the James's Studio; and selected objects under the microscope of Messrs. R. and J. Beck. The house exhibition of photographs by Mr. H. W. Bennett was also visible for the first time, and will be reviewed in our next issue. The function, which, in spite of the inclement weather, was attended by a large number of persons was of a most enjoyable character, and augured well for the open session of the Royal Photographic Society.

## MR. J. T. SANDELL—AN APPEAL.

THE following list of donations received since the appearance of these in our last issue has been sent to us for publication by Mr. Thos. K. Grant, who, with Mr. J. B. B. Wellington, will be glad to receive and acknowledge further amounts:—

	£	s.	d.
Sale of Japine prints from Mr. Sandell's negatives by Platinotype Co., per W. H. Smith .....	1	12	6
Member of Croydon C.C. ....	0	2	6
R.A.C. ....	0	2	6
Leicester and Leicestershire Pho. Soc., per C. W. Leake (Assist. Sec.) .....	1	1	0

## Exhibitions.

## WATFORD CAMERA CLUB.

THE fourth annual exhibition of this club was opened on Wednesday, October 31, by the president (Lord Hyde), and remained open the following day. The judge (Mr. F. J. Mortimer) made the following awards in the open classes:—

Champion.—Silver plaque (No. 5) "October," Fred. Judge. Hon. mention (No. 5) "Gooseberries," Percy W. Morris; (No. 10) "A November Morning," S. G. Kimber.

Landscape, etc.—Silver medal (No. 53) "Roofs of Edinburgh," Arthur W. Walburn. Bronze medal (No. 51) "In Harbour," E. J. Jarvis. Hon. mention (No. 12) "A Lonely Valley," Chas E. Walmsley; (No. 13) "A Summer Sea," Frank Wm. Beken; (No. 21) "The Deserted Ice," Hy. Bond.

Portraiture, etc.—Silver medal (No. 63) "Life's Aftermath," Henry Holt. Bronze medal (No. 93) "The Coquette," Harry Lindoe. Hon. mention (No. 98) "The Butterfly," Aubrey Harris; (No. 86) "The Sick Doll," E. T. Holding; (No. 79) "Diligence," Miss M. E. Wright. Architecture.—Silver medal (No. 107) "N. Triforium, Gloucester," Wm. A. Clark. Bronze medal (No. 111) "A Ray of Sunshine," W. J. Johnson. Hon. mention (No. 113) "The Crypt, Gloucester," S. G. Kimber; (No. 108) "A Sunlit Cloister," W. A. Clark.

Still Life.—Silver medal (No. 120) "A Fruit Study," A. W. Walburn. Bronze medal (No. 130) "Double Daffodils," A. E. Henley. Hon. mention (No. 117) "Shirley Poppies," J. E. T. S. Hilton; (No. 128) "Gooseberries," W. A. Andrews.

Lantern Slides.—Bronze medal: "A Confidential Chat," A. G. Thistleton. Hon. mention: "With Wind and Tide," Miss Kate Smith; "A Dreary Day," J. Ludlam; "Snowdon, Veil'd in Vapour," Graystone Bird.

Any Subject.—Silver medal (No. 143) "The Little Gold Pig," Miss Kate Smith. Bronze medal (No. 142) "Landing the Catch," Miss Thomson. Hon. mention (No. 158) "A Stormy Sunset," Percy W. Morris; (No. 170) "A Deserted Mill," W. A. Andrews.

A PHOTOGRAPHIC society is in process of formation in the Wealdstone district, and should find many members among the employees at the Kodak works. Those interested are asked to communicate with Mr. E. A. Robbins, Newlyn, Bedford Terrace, Station Road, Wealdstone.

ROYAL INSTITUTION.—A General Monthly Meeting of the Members of the Royal Institution was held on the 5th inst., the Duke of Northumberland, K.G., President, in the chair. The special thanks of the members were returned to Dr. Albert P. Brubaker for his present of a portrait of the late Dr. Tyndall, and to Mr. Hugh Spottiswoode for a gift of apparatus.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received from October 22 to 27:—

ETCHING.—No. 23,382. Improved method of etching and apparatus therefor. Eugen Albert, 23, New Bridge Street, London, E.C.

OPTICAL LANTERNS.—No. 23,526. Improvements in optical lanterns. Robert Thorn Haines, Chancery Lane Station Chambers, London.

GLAZING PRINTS.—No. 23,811. Improvements connected with apparatus for burnishing and glazing unmounted photographs and burnishing mounted photographs. James Thomas Eltringham, Lloyd's Bank Building, Canute Road, Southampton.

DEVELOPING TABLE.—No. 23,816. Photographic developing table. William Snow Rogers, Graystroke, Farnham Common, Slough, Bucks.

CINEMATOGRAPHS.—No. 23,904. Improvements in cinematographs. Leo Kamm, 27, Powell Street, Goswell Road, London, E.C.

## COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

COLOURED PHOTOGRAPHS.—No. 5,822, 1906. The present invention relates to the production of coloured photographic pictures by applying a coloured photographic film to a coloured photograph or other base, and its objects are to so carry out the different stages of the process that the photographic film shall be absolutely coincident with its coloured base, and also that softer and better effects may be obtained.

The outlines of a photograph film picture are traced, and this tracing is transferred to the foundation on which the coloured picture is to be produced, such as wood, paper, cloth, ivory, leather, or metal. The film itself is then attached to a support or carrier, as, for instance, paper, celluloid or glass, this support being so prepared that the film may easily be detached from it. For this purpose a coating upon the carrier of gelatine to which tannin or tannic acid or formalin or chrome alum is added to prevent it from expanding or dissolving, has been found suitable, the attached film then being incapable of undergoing any change even when submerged in water. The film thus remains exactly co-incidental with the traced outlines whatever the adhesive employed to connect them together may be. To enable the film to be detached from the carrier the dried gelatine coating is covered with shellac which is allowed to dry, and then coated with a suitable wax, for instance, dissolved in ether. On the thus prepared surface of the carrier the film is placed and adheres until it is sufficiently heated, when the picture becomes detached and peels off.

The copy of the picture obtained from the tracing by transferring it to the foundation to be painted is simply painted in the desired colours. The colours should be carefully smoothed by means of a suitable tool. If the coloured surface were too rough, its appearance would be improved, but would still appear rather rough in the finished picture. The effect of the smoothing may be observed during the painting by simply putting the transparent support with the attached film on the painting to register therewith so that failure is practically impossible.

After the copy of the tracing has been coloured as desired, the film is placed on it in exact register, and is attached to it by means of a suitable adhesive, as, for instance, a solution of shellac or gelatine, to which acetone or other liquid is added in sufficient quantity to soften the film or the picture but not to dissolve it in order that the colours may enter into the softened film, which is very important, as a colour effect is thus obtained which has never before been approached, while a most intimate attachment between the two layers is obtained. The film is then detached from its support.

The adhesive is preferably put on the coloured foundation so that its effect only starts after the film has been put on

and obliteration of the outlines of the picture is avoided. It is easy to observe whether the two pictures actually coincide when using a transparent support or carrier for the film. If the carrier support is not transparent, marks should be provided in order to facilitate the exact putting together of the painted drawing and the film.

Failure in making the drawing and the photograph coincide is almost excluded as neither the tracing nor the foundation, nor the film is liable to shrinkage or expansion, and are therefore bound to coincide. The faithfulness of the photograph remains unimpaired even in the smallest details, and the finished pictures show a freshness of colouring hitherto only obtained in the paintings of artists.

Imitation oil paintings may thus be produced on cloth, imitation water-colour drawings on paper, silk or the like, or imitation miniatures on ivory.

In especially small and fine pictures, the back of the film may also be coloured. This may be advantageously effected by first treating the film with an acetone or similar solution and then colouring the details such as the lips, cheeks, eyes, gold ornaments, lace and the like, these colours becoming fixed by the acetone solution and harmonising with the colours on the foundation when the surfaces are finally united. Carl Pietzner, Z. Mariahilferstrasse, Vienna VI.

**SELF-TONING PAPERS.**—No. 10,051, 1906. This invention relates to self-toning silver chloride printing papers for use in photography. Self-toning silver chloride printing papers prepared from an emulsion containing gold are liable, the inventor states, to spoil if kept in stock for some considerable period. This is especially liable to occur when the paper has been prepared from an emulsion in which the gold is in the form of a chloride; but even when the gold salts employed are free of chlorine, it is not possible directly, that is to say, by means of a sodium chloride bath, the use of which is in all cases considered to be indispensable, to produce tones which, in the well-known tone scale, passing over warm brown or violet-red, approximate to violet blue.

As the result of considerable research, the inventor has, however, discovered that it is possible satisfactorily to prepare an emulsion containing gold chloride, self-toning silver chloride printing papers for which no special toning bath is required. This can be effected by adding to the emulsion one or several lead salts suitable for use in toning, such, for instance, as nitrate or acetate of lead. The use of lead salts in a toning and fixing bath is, of course, not novel; but they have not heretofore been used in the preparation of a self-toning printing paper. By the use of a lead salt in accordance with this invention, a self-toning printing paper prepared from an emulsion containing gold chloride, even in small quantity, can, notwithstanding that it has been kept in stock for a considerable period, be rapidly and satisfactorily toned by means of a bath of sodium chloride; and under precisely similar conditions, that is to say, with the same sodium chloride bath, and the same toning period, there can be produced tones which are much higher in the tone scale, and which approximate much more nearly to violet blue. Good results are, for instance, obtained by the addition to the emulsion for each 100 parts of silver therein from 10 to 16 parts of lead nitrate and from 2 to 5 parts of gold chloride.

The emulsions heretofore usually employed, such, for example, as those of collodion or gelatine are suitable for use in accordance with this invention, the salts of lead being preferably added thereto before those of gold. Oscar Hermann Steudel, Dornblüthstrasse, Dresden.

**SHUTTERS.**—No. 20,800, 1905. The invention relates to photographic shutters of the roller-blind type known as time and instantaneous, more particularly to the well-known "Thornton-Pickard time shutter."

In this class of shutter for time exposures the travel of the roller-blind is arrested (when the aperture therein is opposite the lens)—by a dog or projection on a disc rotated by the roller striking a tooth or projection on the releasing lever.

The inventors find that damage is done to these parts of the shutter by the blind being used for time exposure with a great

amount of tension on the operating spring causing the disc to rotate at a very rapid rate, whereas if it were travelling slowly no such damage would occur.

This invention is designed to prevent the blind being caused to travel at a high speed and only permit of it being travelled at its slowest speed for time exposures.

It consists essentially in constructing the shutter with the releasing lever connected directly or indirectly with the spring click or pawl which holds the spring driven roller, so that when the releasing lever is set for "time" the spring click or pawl will be thrown out of engagement with the ratchet, thereby releasing the spring and allowing it to run off to its lowest tension. The Thornton-Pickard Manufacturing Co., Ltd., George Arthur Pickard, and Frank Slinger.

**DEVELOPING CHAMBERS.**—No. 20,502, 1905. The claim is for a "dark box" in which plates can be developed, bromide prints, etc., made, the whole being portable. Silvius Jean Stefanescu, Kudsir, Hungary.

## New Books.

**"Künstlerische Landschafts-Photographie"** (Artistic Landscape Photography). By Geh. Reg. Rat. Dr. A. Miethe. Halle: W. Knapp. M. 8.

This is a very sumptuous book, the letterpress of which has the aspect of a Kelmescott edition; but the numerous cuts have suffered by over-inking. Dr. Miethe is well enough known in the scientific paths of photography, but many will be surprised by his entry into those of art. He has proved, however, that the task sits easily upon him. This is a second edition, revised and enlarged, of work carried out with German thoroughness. No point of pictorial importance seems to have escaped the author. He says that the book is intended for those who have mastered technical difficulties nevertheless Chapters 2 and 3 deal with apparatus, and another with perspective. Dr. Miethe can be studied with interest in such matters as Light, "Motive," Mood (Stimmung), Air and Water, of which he says that the old school treated them with stepmotherly neglect. His concluding words regarding "Manner" are worth quoting:—"We consider it false and unworthy of landscape photography to obtain, by the help of handwork on the finished picture an effect which was absent in the original."

MESSRS. HENRY SOTHERAN AND Co., 140, Strand, London, W.C., have issued Part I. of their "Bibliotheca Chemico-Mathematica," a list of old books on chemical and general scientific subjects. The list goes as far as G, and includes Daguerre's "Historique et Description des Procédés Daguerreotype et du Diorama," the first work on photography in any language, and now very scarce. P. H. Delamotte's "Practice of Photography" is another of photographic work included. Students of the early history of photography may bear in mind the publication of the later portion of Messrs. Sotheran's list.

## CATALOGUES AND TRADE NOTICES.

Mr. R. R. Beard, the well-known lantern expert, of 10, Trafalgar Road, Old Kent Road, London, S.E., has issued a new price-list of lantern and cinematograph apparatus, the majority of the articles being manufactured by himself.

MESSRS. A. E. STALEY AND Co. have at the disposal of members of the photographic trade an interesting book published by the Bausch and Lomb firm, describing the manufacture of lenses in all its branches. The volume, which is excellently "produced," will be sent to anyone in the trade for 3d., or to other applicants for one shilling.

THE Hackney Exhibition opened on Wednesday in the King Hall, Hackney Baths, N.E. There is a good trade show and strong showing of members' work, of which we will write in our next issue. We advise all our London readers who can do so visit the exhibition, which closes on Saturday evening at 10 p.m.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—"Architectural Photography: What to Take and How to Take It." was the subject of a lantern lecture, on the 5th inst., by Mr. H. Creighton Beckett. The lecturer having described the apparatus requisite for successful work, proceeded to give much useful information on the general subject of architectural photography, illustrating his remarks by an imposing array of upwards of 200 slides. Architectural subjects are usually improved by being taken at an angle instead of full on. It is also frequently advantageous and conducive to a pleasing picture to include some of the surroundings. Interior views are often greatly improved if taken when the sun is shining and the composition is so arranged that patches of sunlight break up spaces otherwise dull and uninteresting. The camera should never be placed in the centre of a nave or aisle, and should be kept as low as possible, never above eye level. Arches should always be shown

complete. Compose your pictures of interiors so that the brightest high lights are nearest the deepest shadows. Over, rather than under, expose. The various styles of architecture—Saxon, Norman, Early English, and Gothic—were described and illustrated. Detail work in the shape of capitals, ceilings, fonts, tombs, gargoyles, sanctuary knockers, bench ends, etc., to which Mr. Beckett has given special study, was indicated as one branch in which the photographer of architecture might find endless scope for useful and interesting work.

**SOUTHAMPTON CAMERA CLUB.**—On November 5 Mr. W. Farren, of Cambridge, lectured on "Wild Bird Life With the Camera." The lecturer pointed out the common instinct of the sportsman and the naturalist-photographer in the pursuit of the wild bird life of the country, and claimed for the latter equal pleasure in the pursuit without the destruction which the former brought about. In a series of unique slides, numbering over one hundred, Mr. Farren portrayed the habits of many of our wild birds, and detailed the habits and home life of not only the better known but the more rare species, an especially successful set being that pertaining to the snipe. The plover family, so difficult to deal with in this way, and the various families of our sea-birds all received attention, and in a manner which gave only a slight realisation of the immense patience and skill required to produce the results achieved. Mr. Farren dealt with the photographic side of the work for the benefit of the members in thorough fashion, among his points being the following:—In place of setting up the camera and depending on a long rubber or electric release, he advocated the use of the tree trunk tent, an erection of a small framework with a canvas cover painted roughly to resemble a tree trunk, in which the worker may be concealed, the deception of which might be heightened by the aid of a few branches arranged round it. He stated that with care this enabled the worker, though cramped somewhat, to be in close proximity to the nest of the bird, and that experience proved that the birds readily used themselves to such a structure. He warned the naturalist-photographers never to be in a hurry, and impressed upon them the advantage of using the single combination of their lenses, which increased the focal length from the ordinary nine inches to that of fourteen, and showed a number of slides illustrating the difference between the one method and the other. In the matter of baiting for the attraction of birds of the town-garden order, he advocated the use of soaked bread as preferable to the crust variety, for the reason that the birds decamped with the latter and spoiled the photographer's opportunity, while the soaked variety kept them hard at work picking up sufficient quantity.

**CROYDON CAMERA CLUB.**—Mr. Braham, of the Autotype Company, who is quite an old friend at Croydon, on the 31st ult. gave a capital exposition of the carbon process. With a range of over thirty colours to select from, the worker must be hard indeed to please who cannot find one or the other appropriate for the subject, especially as each colour can be modified largely by employing tinted or coloured supports. Even rather an outré base, such as silver, looked well, and gave a realistic print (forming a trade card) for silverware and spoons, as did a "flaming red" in firelight scenes. A short cut to pictorialism is also provided by texture films. By means of these ingenious contrivances a carbon print can be made to resemble a coarse or fine line half-tone block at will; and a dead smooth paper to approximate to a rough one very closely. Apart from these, and possibly other facilities, the films would doubtless afford broad effects by mechanically suppressing excess of detail. A large number of beautiful Autotype prints for the time being adorned the club walls, including the inevitable but invariably pleasing "Sleepy Hollow." A most hearty vote of thanks was accorded Mr. Braham. In the course of the evening the President, Mr. W. H. Smith, announced that the Platinotype Company had with pleasure consented to furnish prints to members, from 15 x 12 negatives, taken by Mr. J. T. Sandell in Italy. These would be for sale at a certain price, the entire amount realised to be devoted to the fund now in existence. The Adhesive Dry Mounting Co. had also kindly undertaken to mount the prints without charge. Many availed themselves of this offer.

**NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.**—At the annual meeting of the above Association, held October 31, the following officials were elected for the forthcoming session:—President, J. W. Dyson; Vice-Presidents, W. E.

Cowan, J. J. Kirkwood, W. Dotchin, J. H. Holmes, Arthur Payne, F.C.S.; Council, W. Parry, W. S. Corder, W. D. Cookson, D. A. Lowery, T. M. Clague, E. Holmes, Douglas Waite, E. G. Lee, J. Hume Harbottle, David Thomas; Hon. Lanternist, T. Bulman; Auditor, T. M. Clague; Secretary, F. Milburn, 75, Rothwell Road, Gosforth, Northumberland; Assistant Secretary and Treasurer, Arthur Scott, 9, Myrtle Grove, West Jesmond, Newcastle-on-Tyne. The Association has now made arrangements to hold meetings at the Armstrong College. Meetings are now held on Wednesdays instead of Tuesdays.

**SWANSEA CAMERA CLUB.**—The annual general meeting of the Swansea Camera Club was held at the Society's rooms, 15, Temple Street, last week. Mr. J. Trevor Owen, M.A., presided, and a large number of members attended to elect officers and arrange the winter programme of lectures, competitions, etc. Mr. J. Trevor Owen was unanimously re-elected president, Messrs. P. Courtois and W. R. Stephens were elected vice-presidents, Mr. R. David Burnie secretary, and Mr. J. P. Robinson assistant secretary and treasurer.

## New Materials.

**Actinos P.O.P.** Sold by the Lumière N.A. Co., 4, Bloomsbury Street, W.C.

The special feature in this paper is that the emulsion contains no free soluble silver salt; there is, therefore, no possible chance of silver stains on negatives when printing in damp weather, and the paper should keep well.

Its treatment in no way differs from that for ordinary P.O.P. containing free silver. Printing must be carried to the usual depth, and the prints well washed prior to toning, which may be effected either in the combined or separate baths, with gold or platinum or both.

The intensity obtainable with this paper is good, and the gradation satisfactory. We should call it decidedly a brilliant working paper. There is some loss in the operations of toning and fixing, but the whites keep clean. The paper can be obtained in three surfaces—glossy, matt, and rough art, and for large subjects the last is a very pleasing texture.

**CHRISTMAS Greeting Postcards.**—Messrs. Wellington and Ward send us specimens of their series of bromide, S.C.P., and P.O.P. postcards, bearing inscriptions of a suitable Christmas character on the address side. The P.O.P. cards are sold at twelve for 6d., the others at eighteen for 1s.

## News and Notes.

**MR. LANG SIMS**, Brixton, S.W., has been again returned in the Borough Council elections.

**HYPERFOCAL DISTANCE.**—In reference to Dr. Lindsay Johnson's recent communication to the "Journal of the Royal Photographic Society," a correspondent sends us a reference to "The Photogram" (now "The Photographic Monthly"), for 1904, p. 229, in which the identical short cut to calculation suggested by Dr. Johnson is given by Mr. A. Mackie. The paragraph is as follows, from which it will be seen that Mr. Mackie corrects the approximate results obtained by the rule in the form given by Dr. Johnson, by adding half an inch for each foot:—"All calculations connected with depth of field are based upon the hyperfocal distance, that is to say, the nearest point which must be focussed in order to obtain all objects behind it in apparently equally good focus, and this distance differs materially according to the focus of the lens, the size of the stop, and what is allowed as the diameter of the diffusion disc of a mathematical point. The diffusion disc for ordinary photographic work is usually taken at 1-100th of an inch. The mathematical formula as given in the text-books is not a difficult sum, but my own adaptation of it reduces the calculation to one of mental arithmetic. I say my own adaptation, because I have never heard of any one else using it. It is:—Square the focus of the lens in inches and take the result as feet. To be exact, there should be added half an inch for each foot. That will give the hyperfocal distance of the lens at  $f/8$ . For example, a 5-inch lens will be  $5 \times 5$  in. = 25 feet + 25 half inches = 26 feet  $\frac{1}{2}$  inch. For other stops the distance is in direct proportion to the stop diameter, and the rule is:—Multiply by a fraction, having 8 as the

numerator and the stop fraction as the denominator, thus:— $f/4$  8-4 or 2;  $f/16$  8-16 or  $\frac{1}{2}$ ;  $f/32$  8-32 or  $\frac{1}{4}$ , and so on. The intermediate stops, which include decimal fractions, involve a few more figures. To the user of a stand camera calculations relative to depth of field are comparatively unimportant; he can adjust his stop to suit the picture as he views it on the focussing screen, but to the user of the hand camera they are all-important. The whole question of depth of field is so lucidly treated in "The Lens," by Thomas Bolas, F.I.C., and George E. Brown, F.I.C., in the chapter devoted to the subject that it is a very practical hint to refer my readers interested in the subject to the book."

**SHEFFIELD Photographic Society Exhibition.**—The prospectus for the forthcoming exhibition in February next, at which Mr. Chas. Bayley will be the only judge, has been published, and is obtainable from the Secretary, Mr. James W. Wright, 62, Vale Road, Sheffield. The Society has made arrangements for the free carriage of exhibits between the Sheffield, Nottingham, and Leicester Exhibitions, and has also instituted reduced fees for exhibitors at all three towns. One entry form only is required for all three shows.

A MEETING of the National Photographic Record Association will be held at the Midland Grand Hotel, St. Pancras, Wednesday, November 14. Afternoon tea will be served at four o'clock. A report will be presented and a discussion invited upon "Record Work," and a collection of photographs by Sir J. Benjamin Stoddart and other members of the Association will be exhibited.

**COLOUR Photography.**—A small exhibition is being held this week at 43, Basinghall Street, London, E.C., of carbon three-colour prints by Mr. Otto Pfenninger, of Brighton, by whom all the negatives have been taken and the prints prepared on "Autotype" tissues. This exhibition, we are informed, is to demonstrate the possibilities of Mr. Pfenninger's camera for one-lens one-exposure colour photography, the inventor's object being to come into touch with those interested in placing the apparatus on the market. A number of the specimens shown were exhibited at the exhibition of colour photography at our offices in the spring, where they attracted some unfavourable comment. We are therefore glad to see in the collection at Basinghall Street a number of later prints which are fine in advance, technically, of those previously exhibited. Mr. Pfenninger will be in attendance until Saturday next, on which date at four o'clock, the collection will be removed. The collection will be on view, however, the next week, November 12 to 17, at the Photographic School, Polytechnic, Regent Street, W., by courtesy of Mr. Howard Farmer.

At the recent Milan Exhibition the firm of Dr. J. H. Smith and Co., of Zurich, represented in this country by Mr. Oliver Dawson of 254A, High Holborn, were awarded a gold medal for their photographic plates, films, and papers.

**THE Society of Colour Photographers.**—In accordance with the resolution passed at the meeting held at the offices of the BRITISH JOURNAL OF PHOTOGRAPHY on October 16 last, members of the newly formed Society of Colour Photographers are asked to attend a meeting at the same address on Thursday next, November 15, to receive the draft of the rules and recommendations drawn up by the committee and already published in the press. It is intended that the meeting be open only to members or those seeking membership. The time is fixed for 6.30 p.m.

**MR. R. LAUSTE**, of the Warwick Trading Company, is at present in Mombasa, Uganda. Mr. Lauste has already sent home some 2,000 ft. of films containing moving pictures of Mombasa City and of the Freretown C.M.S. Station. He will take pictures of our railway and the game herds on the plains; he will also visit Uganda and Lake Victoria Nyanza. The Colonial Office has granted special privileges to the Warwick Company so as to assist their agent in obtaining the best views the country affords. Mr. Lauste expects to secure some 30,000 ft. of films before returning.

A GREAT photographic exhibition is to take place in Dresden from May to September, 1910. It will not be confined to pictorial and scientific photographs and apparatus, but is intended to afford a comprehensive view of photographic art industry to its full extent. The making of cameras, the working of optical and process establishments (for heliogravure, phototype, rotary reproduction, etc.), will be shown in operation on the premises. The interest of public authorities has been secured for the exhibition, and distinguished specialists as well as reputed firms in Germany and abroad have promised the

support. The active co-operation of photographers' associations and photographic periodicals of every country will be invited, that the great object in view, a complete representation of photography, may be successfully attained. The management of the undertaking has been entrusted to the Deutscher Photographen Verein (German Photographers' Association), which is engaged with the preliminary arrangements in union with the Dresden Society for the promotion of Amateur Photography, and a considerable number of makers and dealers.

**Stoves for the Studio.**—Messrs. R. Beckett and Son, The Grove, Hackney, N.E., write us:—"Referring to your article on the warming of studios, we beg to draw your attention to enclosed list of gas stoves which we are putting on the market. They give a maximum heat with a medium amount of gas, and are guaranteed absolutely odourless. The prices, as you will see, are very low, and stoves are made to heat rooms from 7ft. square up." We suggest to our readers that many of them might do well to apply for the list of heating appliances.

**MESSRS. SANDERS AND CROWHURST, 71, Shaftesbury Avenue, London, W.,** have issued a new descriptive price list of the "Southport" enlarging table.

## Commercial & Legal Intelligence.

**PHOTOGRAPHIC Trade Mark Action.**—Mr. Kerby, in the London Chancery Division, on Nov. 2, before Mr. Justice Kekewich, said he had a motion on behalf of Kodak (Limited), for an injunction to restrain Mr. Grenville, a gentleman carrying on business in Corporation Street, Birmingham, from infringing the plaintiffs' trade mark known as "Brownie" films, which was the plaintiffs' registered trade mark. Counsel said there had been a good deal of litigation about this particular trade mark, but it had been decided, before Mr. Justice Swinfen Eady, that the plaintiffs were entitled to an injunction in cases where the parties sold photographic films other than the plaintiffs' when asked for "Brownie" films. Mr. Kerby read affidavits showing that a messenger was sent to defendant's shop in Birmingham for a Brownie film, and that he was supplied with another film, which was not of the plaintiffs' manufacture. Mr. P. Hayden Lawrence read affidavits on behalf of the defendant, to show that the messenger who went for the film was told that there were no Brownie films in stock, and was asked if another film would do. He said that it would. Mr. Justice Kekewich said that as at present advised he did not see where infringement came in, and as there was no urgency in the matter, he said he should make no order on the present motion, except that the costs of the motion be costs in the action.

**MR. CHAMBERLAIN'S Photograph.**—At the Birmingham County Court last week, before his Honour Judge Bray, E. H. Harris, printer, Constitution Hill, sought to recover £1 14s. 6d. for printing from Stewart E. Smith, lithographer, Jamaica Row, while the defendant counter-claimed for £7 13s. 2d. for loss alleged to have been sustained through the negligence and bad workmanship of the plaintiff. The case had reference to the printing of the portrait of Mr. Chamberlain in the centre of a decorated card bearing the words, "Souvenir of the celebration of the Right Hon. Joseph Chamberlain's birthday, and thirtieth year of Parliamentary representation of Birmingham." The plaintiff explained the rush with which the cards had to be produced, and maintained that those printed were up to sample. Mr. A. Ward (instructed by Mr. H. C. Edwards), who appeared for the defendant, produced one of the cards for inspection, and in cross-examination of the plaintiff pointed out that there was not a line across the sample, but, he added, "On those printed you give Mr. Chamberlain a mustachio." His Honour found for the plaintiff on the claim, and gave judgment for £5 15s. on the counter-claim.

### NEW COMPANIES

**PHOTOGRAPHIC NOVELTIES SYNDICATE, LIMITED.**—Capital £2,000, in 10s. shares. Objects: To adopt an agreement with R. M. Houldsworth, and to carry on the business of manufacturers of photographic novelties, manufacturers of picture postcards, etc. No public issue. Registered without articles of association.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE OZOBROME PROCESS.

To the Editors.

Gentlemen,—Referring to my recent letter on the Ozobrome Process (B.J., Oct. 12, p. 816), I have now tried the suggested addition of potassium citrate to the solution with a view to obtaining increased contrast, but cannot at all recommend it. Its action, even in very small quantities, is to cause all the lighter gradations to wash away in development, with the result that the gradation ends abruptly in the half-tones and the lighter gradations are absent. This gives an apparent increase of contrast, but at the expense of all truth of gradation.

There is one very important point in connection with Method I., or Non-transfer Process, to which attention is not drawn in the Ozobrome instructions, and that is that the bleached image beneath the carbon picture must either be removed by hypo and ferricyanide reducer, or else re-developed with developer or sulphide solution. The reason for this is that the bleached image is sensitive to light, and will in a short time, by exposure to light alone, become blackened almost to its original state. The Ozobrome instructions simply say:—"Should any of the black silver deposit remain under the gelatine in the very deep shadows, it may be easily removed by the ferricyanide and hypo reducer"; and again in the addenda to the instructions:—"In Method I. the bleached image beneath the carbon picture may be re-developed partially or entirely"; but I wish to lay stress on the necessity of either removing or re-developing this bleached image, as otherwise the print will entirely alter by exposure to light. It seems to me the only satisfactory way to make use of this bleached image in order to modify the picture would be to re-develop it entirely, and then remove portions of it with the reducer.—Yours faithfully,

S. C. PUDDY.

Arrington House, 87, Crouch Hill, N., November 6, 1906.

### THE STABILITY OF THE PYRO AND SODA DEVELOPING SOLUTIONS.

To the Editors.

Gentlemen,—In common with the rest of your readers I am keenly interested in your articles on the pyro-soda developer, and in connection with your comparative table and remarks thereon in to-day's issue, the following incident may be of interest.

I have been in the habit of using a pyro-soda developer that approximates as nearly to Mr. Bennett's formula as Mr. Herbert's does to yours, viz.:—

Pyro .....	1½ grs.
Potass. metabisulphite .....	½ gr.
Soda sulphite.....	11 grs.
Soda carbonate.....	11 grs.
Potass. bromide .....	½ gr.
Water .....	1 oz.

I do not know if I mix it differently in some detail, but I certainly do not find it keep as Mr. Bennett finds his, and some twelve months ago, having only a small batch of plates to develop, I made up only one-fourth of my usual quantity of solutions, but inadvertently weighed out metabisulphite for a full quantity.

I thus had four times the usual proportion, viz., two grains instead of half grain metabisulphite to the ounce of mixed developer, and the result considerably astonished me.

I always time first appearance of image, and with the above developer this takes place pretty generally in 40-50 seconds, development being complete in about five minutes.

With the developer containing the extra quantity of metabisulphite

the appearance of the image was delayed to such an extent that I concluded I must be developing an unexposed plate, and was on the point of putting it aside when I saw traces of it coming up.

Development prolonged to 20-25 minutes gave a negative distinctly less dense than the usual developer gave in five minutes.

Several plates behaving in the same way, the operation became too tedious and unsatisfactory, and I threw the developer away and mixed fresh solutions on the usual lines, and the rest of the plates developed quite normally.

As the proportion of metabisulphate was the only one varied, it would certainly appear that in a given proportion it acts as a powerful restrainer, and would not that theory coincide with your own experience with the developer you recommend before you increased the pyro and carbonate.—Yours faithfully,

R. E. WESTON.

Grove Lodge, Clarendon Road, Watford.

November 2, 1906.

#### To the Editors.

Gentlemen,—With regard to the notes which have appeared in recent issues, will you allow me to point out that litmus is not the most suitable reagent for testing the alkalinity or otherwise of sodium sulphite. Phenolphthalein is better, and if this be used it is quite possible that the neutral sodium sulphite solution will not be found neutral.

I venture to point this out because metabisulphite, being an acid salt, will, if pure, neutralise no less than 0.96 per cent. of the sodium carbonate crystal. Now, I can only imagine that carbonate can be the only alkaline salt in sulphite, and therefore 2 grains of metabisulphite would neutralise 1.92 grains of carbonate, and would mean that more than one-fifth of the sulphite was carbonate; surely this could not happen.

With regard to the note in your last issue, p. 863, as to Mr. Bennett's developer acting more rapidly, can this not be ascribed to the action of the bromide? When using Watkins' time development system, which I always do, I have found that invariably the addition of bromide reduces the factor, and this is shown by the following extract from Mr. Watkins' excellent little "Manual."

Grains pyro per oz.	Factor.	Bromide per oz.	Factor.
1	18	$\frac{1}{4}$	9
2	12	$\frac{1}{2}$	5
3	10	$\frac{3}{4}$	$4\frac{1}{2}$
4	8	1	4

Now as all three formulæ given by you have only  $1\frac{1}{2}$  grains pyro per oz., the factor would be 15 and 7 respectively. Would this not explain the anomalous behaviour of Mr. Bennett's developer?—Yours faithfully,

ARTHUR GASCOIGNE.

London, E.C.

[We are obliged to our correspondents for the above suggestions, which will all be subjected to tests when we take up the further experiments. With regard to the neutralisation of the sulphite, there is probably a little carbonate present, though barely enough to detect. Independently, however, of the presence of carbonate, soda sulphite has an alkaline reaction, and so the question is somewhat complicated. The alkaline nature of the sulphite is noted by both Bloxam and Tilden. No doubt bromide lowers the factor, but it lengthens the time of appearance, and we can hardly realise that it is likely to considerably shorten the total time of development. Mr. Weston's experience is on all fours with ours, and is equally curious. We assume that he preserves the pyro with metabisulphite, and keeps the sulphite in the alkali bottle, in which case the want of stability is explained.—Eps. B.J.P.]

#### FOCUSING SCALES.

##### To the Editors.

Gentlemen,—A graphic method of delineating focussing scales appeared—I believe towards the end of last year's issue—in your Journal which was based on the principle of obtaining five inches of the required scale by actual test with the camera. The method was simple, but unfortunately not accurate, the errors being greater in the longer focal lengths, where accuracy is more essential, owing to the less apparent depth of definition they give on

the focussing screen, the error for an object ten feet distant amounting to upwards of 1-5th of an inch for a lens of twelve inch focus—a serious discrepancy. This is shown on the diagram below, which, for the sake of comparison, is superimposed on the diagram of my method, which is shown correctly on the right of CD; in juxtaposition with the other graphic method, the value showing the amount of error. This is the diagram of a focussing scale for a lens of twelve inch equivalent focus, and its correctness may easily be verified by the data given below.

The error diminishes as the focal lengths become shorter, is only .017 of an inch for a lens of six inch focus, but is never less incorrect; and in the present state of photography—where focussing by scale is coming daily more to the fore—not up-to-date—doubtless it has proved useful for the shorter focal lengths, thus justified its existence; but the advent of an exact method is my apology for troubling you at what I imagine must be a busy period of the year.

The diagram (enlarged up to 2 diameters) and description explain themselves, and will be endorsed with this letter.

If the diagram is reduced to exactly  $\frac{1}{4}$  the size—i.e., half scale—it will give a working focussing scale for a lens of six inch focal length, and might prove useful to those having lenses of this equivalent focus.

Trusting that the enclosed may prove of interest to you, remain, yours truly,

JULIUS H. HOMAN, Civil Engineer,

Vice-President, Mosman Photographic Society,

Redcot, Lennox Street, Mosman, Sydney, N.S.W.,

September 28, 1906.

[The article referred to by Mr. Homan appeared in our issue of June 1, 1906, and it was followed by a letter from Mr. Braniff of June 15, raising almost the same points as are called in question by Mr. Homan. Mr. Homan is mistaken in his assumptions as to our graphic method, which is absolutely accurate, as stated in the article itself. The trouble is that Mr. Homan omitted to observe that the distances given by our method are extra-focal distances measured from the front principal focus of the lens, while those given by his method are nodal distances measured from the entrance node of the lens. Therefore, if he wishes to check our method by his he must add one focal length to our distances. With a twelve-inch lens the mark on the scale that represents an extra-focal distance of, say, seven feet also presents a nodal distance of eight feet. Owing to this miscomprehension of our method, the figures given in his comparative table are all wrong and meaningless. We must congratulate him on the diagram given in his article, which, as we know from experience, represents the solution of a very difficult problem. He gives proofs, but, the results being accurate, we assume the diagram to be correct. Its complexity, as compared with the simple diagram given in our article, shows the great disadvantage of measuring conjugate distances from the nodes. If extra-focal distances alone were considered, all problems relating to conjugates are perfectly easy while the use of nodal distances renders the simplest problem unnecessarily complex. We fear that Mr. Homan's diagram is too

complex to be of use in drawing an actual scale, which with short focus lenses is a very minute affair.—Eds. B.J.P.]

## THE SENSITOMETRY OF PLATES.

To the Editors.

Gentlemen,—In reference to my letter published in your issue of October 26, and stating the value which, in my experience, screened acetylene light has in testing orthochromatic plates, I send some results which will confirm what I said. They are reproductions of two sets of sector-wheel exposures: (a) on a panchromatic plate; and (b) on an ordinary extra-rapid plate. The exposures (1) are to unscreened acetylene, and it will be

you that the panchromatic gives the same number of sectors as the ordinary plate; (2) are to screened acetylene, and it will be seen that the panchromatic is only half the speed of the ordinary; (3) to daylight, and give results practically identical with b.—Yours faithfully,  
C. E. KENNETH MEES.  
Croydon.

Stage Photography.—A great fuss is made in the "Manchester Spectator" of a photograph by Mr. F. Fielding, reproduced in our contemporary's pages on the 31st ult. It foreshadows, we are told, a revolution in winter and indoor photography." and refers to the experiments of the photographer, who "by means of a special dye has so increased the sensitiveness of an ordinary photographic plate as to make it, in artificial light, from 20 to 30 times as rapid as the quickest commercial dry plate. The dye process, has, of course, been the subject of experiments for years by many photographic chemists, but this Manchester gentleman has obtained exceptional results. This photograph was taken from the dress circle of the theatre with an exposure of 1-10th of a second, with a lens aperture of F8. No flashlight was used—nothing but ordinary lights of the stage. With the full aperture of the lens the photograph could have been taken with an exposure of 1-40th of a second. With the quickest of unprepared plates the exposure necessarily would be, under the best circumstances, at least 10 seconds." The photograph represents one of the "living statuary" now being shown in many music halls, the living model posing for, perhaps, half a minute. Why, under these circumstances, it should be thought desirable to give an exposure of one-tenth of a second it is difficult to understand. We should say that the process, thus extolled, consists simply in the use of a home bathed or a commercial bathed plate, as described in our pages by Mr. Arthur Payne in July last.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

\* \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

E. V. Parkin, 58, Wilkinson Street, Sheffield. Two Photographs of the Sheffield United Football Team.

W. E. Lewthwaite, 1 Park Road, Blackpool, Lancs. Photograph of the County Borough of Blackpool. Roll of Honour.

A. Lamb, Newsagent, Gowthorpe, Selby, Yorkshire. Photograph of Miss M. J. Hodgson.

T. C. Bowyer, South Ascot, Berkshire. Photograph of Raglan Castle.

A. Barton, 74, Stratford Road, South Acton, London, W. Photograph of the Clergy Staff at All Saints' Church, Acton, London, W.

T. Taylor, 33, St. Albans, Liverpool. Photograph of the Liverpool Association Football Team, Season 1896-7.

INSURANCE CLAIM.—I have recently had destroyed by fire, amongst a few other things, about 2,000 cabinet negatives. The damage was not very great in all, but the negatives are quite spoilt; but the Insurance Company seems to regard them as of no value whatever, as they were not in use, and only valuable in case of a re-order. I do not know how the matter generally stands in the case of negatives destroyed by fire, and should be glad to know if you can advise me as to whether I can claim for them.—G. W.

Without seeing the policy or knowing its conditions, we cannot express an opinion. If negatives are insured in the policy you can certainly recover something for them.

TINSELLING POSTCARDS.—Could you tell me the name of a firm where I can get the materials for tinselling or jewellery postcards, such as are on the market at present?—HUDDERSFIELD.

The Vanguard Manufacturing Co., Maidenhead.

STATUS.—A small tradesman in this district has for some years attended all sports, race meetings, and other events, sends prints to all the illustrated papers, obtains fees when used, and sells copies in large numbers to stationers and other postcard printers, and again receives 7s. 6d. to 10s. 6d. each subject. Will you kindly let me know if, in your opinion, he is qualified to enter a class of photography in a local exhibition as an amateur, and take prizes in a section in which he would compete with those who practise photography as a pastime only?—CURIOUS.

We should not disqualify him. He does not depend upon photography for his livelihood. Surely you do not suggest that payment for occasional photographs to newspapers or postcard publishers constitutes a man a professional photographer.

VARIOUS QUERIES.—I shall be much obliged if you will supply me with (1) a formula for a platinum bath which gives greyish-black or warm black tones on Collodio chloride paper. The baths I have used tend to throw brown, reddish or purplish brown, or cold black tones. 2. Can you inform me why the term "carbon" is applied to the process of that name? 3. Kindly let me have a formula for a bath to reduce high lights on film negatives. I have tried ammonium persulphate, but can obtain hardly any reduction, even though the films were allowed to remain in the bath with a glass negative, until the image on latter completely vanished.—GEOFF.

1. If you can get the tones you mention with the bath you are using, you should be able to get those you desire by stopping the toning at a different stage. You do not say if you use a preliminary gold bath, if so, carry the toning in that to a deeper stage. You should bear in mind that the tones yielded depend more upon the character of the negative than the formula for the

toning bath. 2. Because carbon is the principal pigment used, and from that the process took its name. 3. The persulphate of ammonia works as well with films as it does with plates, and we cannot see how you have failed with it, as you give no particulars as to how you have used it.

**PROCESS WANTED.**—I have coloured for a customer of mine some mother-of-pearl by the silver process, exposed to light, after which it becomes a nice steel colour. My customer now wants me to get a sepia colour something like self-toning paper. I should esteem it a great favour if you would kindly give a process to get the sepia colour.—F. P. HITZER.

We cannot understand from your letter what you mean by coloured mother-of-pearl by the silver process, which is of a steel colour. If you desire to produce sepia, or any other, colour pictures on mother-of-pearl, or other material, you can do it by the carbon process. Possibly that will meet your requirements.

**LIGHTING.**—You will find an article on mercury-vapour lamps in the "Almanac," 1906, p. 745. One on the Westminster arc lamps has appeared in our pages this year. See our advertisement pages for the names of firms.

**BACKING.**—1. Will you kindly inform me where I can obtain "Caramel"—the lump, I believe—for backing dry plates, as I understand that the burnt sugar preparation is of no use. 2. In making backing, will methylated spirit serve as efficiently as alcohol? 3. Please advise good book on framing.—T. V. B.

1. Lichtenstein and Co., Chemical Works, Silvertown, E.  
2. Yes. 3. "Mounts and Frames," by the Rev. F. C. Lambert (Hazell, Watson, and Viney), 1s.

**LENS QUERY.**—1. I have a lens offered me, working at  $f/5$ , and bearing the name of Henry Crouch, London. Kindly inform me whether he is a good maker and if the lens is suitable for all-round photographic purposes? 2. Also, can you tell me where I can procure, in London, photographic brasswork and woodwork?—NERO.

1. Henry Crouch has a good name as an optician. You do not mention the form of the lens you have offered you, whether of the Petzval portrait, or the R.R. type. A lens of the latter form, working at  $f/5$ , is a useful one for general purposes. If, however, it happens to be of the Petzval type it is better adapted for portraiture than for anything else. Better try it and see if it will answer the purpose for which you require it.

2. The Kodak Company, Clerkenwell Road, supply brass fittings for cameras, etc., but we are not aware whether they supply the woodwork. We rather think not.

**STUDIO QUERY.**—I am shortly to be building a studio, and, having the choice of two positions, should be greatly obliged for your advice as to which is the better of the two. At the one I could have a studio on ground floor with a north light, but premises are not in the best position for business. At the other the studio would have to be on the first floor. Could get a good length and width, but the light would be a west light, as the east side is too close to adjoining property. This latter is in the best position for business, and much better premises. Would an ordinarily constructed studio, with ground glass, answer, or should it be specially constructed to make this light workable?—STUDIO.

By all means decide on the premises that are in the best position for business. A west light is an exceedingly good one to work in. It is quite a fallacy to suppose that good work can only be done in a studio with a north light. The only advantage of that aspect is that the light is rather more uniform throughout the day, but that is of little moment to a photographer who understands his work. Amongst some of the best portraits we have ever seen were some that were taken in studios with a south light. The late Mr. Valentine Blanchard, and the late Adam Salaman, of Paris, preferred a south light to any other, and had studios constructed with that light. Either ground glass or plain can be used, and the latter is the cheaper of the two; but the former will be the preferable if the studio will be much overlooked by the neighbours.

**ARTICLE.**—May I ask if you would kindly inform me whether, and if so at what date, an article has appeared in the BRITISH JOURNAL OF PHOTOGRAPHY on "Lens Rapidity," by F. Grenfell Baker, since October, 1904. I would not trouble you about this,

but being away from all means of reference and files of JOURNAL, I cannot otherwise obtain the information I require. VIATOR.

"Lens Rapidity," September 9, 1904, is the only article which has appeared.

**TONING VIGNETTES.**—2. I shall be very much obliged if you can give me some advice on a toning trouble. Can you tell me how to prevent the margin of a vignette or the high-lights on a white dress from giving a nasty yellow colour, fading into purple at the edges. I use a sulphocyanide and gold bath, and then pour it away, but add sulphocyanide each time I have finished toning, and gold just before I start next time, and also as the bath weakens during a batch of toning. It is impossible to get a good blue tone, as when the prints get to a certain pitch of discoloration appears and they have to be fixed or it will be so pronounced. I do not suffer with double tones—that is, by all sorts of tones in patches, due to too quick a bath, cannot get to the root of the evil. Can you give me a good formula in good, large quantities—say, enough to tone a glass of cabinets or thereabouts?—S.E.

1. We cannot. 2. Your experience arises, we should think, from an imperfectly ripened bath. We think you would be rid of the trouble if you were to work on the system of definite quantity of fresh but ripened bath for each batch of prints. According to your present method, you are constantly working the bath too weak, and very probably have too much sulphocyanide in it. We should advise you to adhere to the maker's formula.

**SAFE LIGHT.**—You said, some time ago, tartrazine 2 parts, and bengal 1 part, made a good liquid dark-room lamp. I find these things are dry powders. What strength should the solution be for a given thickness of solution (I mean the amount of the solution the light shines through) to make a safe light?—E. H.

The thickness of solution is of no moment; what one has to determine is the area of the tank, and to every square inch should be allowed one-tenth of a grain of tartrazine and one-twentieth of a grain of rose bengal, dissolved in distilled water. Assuming that the face of the tank measures 10 by 10 in., it is obvious that the quantities of dyes would be 10 and 5 grains respectively, and it would be immaterial whether these amounts were in a thickness of 1 in. or 3 in., the spectrum absorption would be the same. Theoretically, of course, water has some absorption, but this can be ignored.

**FIREPROOF FABRIC.**—Could you kindly let me know any solution that may be applied to ordinary linen to make it sufficient fireproof for use with a flash-lamp; or where I can obtain material ready prepared?—A SUBSCRIBER.

If our correspondent will refer to p. 722 of our issue of September 16 he will find a list of salts which are efficacious. It is also pointed out there that Professor Vivian Lewis finds a mixture of ammonium phosphate and borax as efficacious as any. If a saturated solution of each be made and mixed in equal parts, and then diluted with an equal quantity of water the results will be satisfactory.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

A French worker, M. André Cheron, describes his experiments in direct colour-photography by prismatic dispersion on the lines of Dr. Julius Rheinberg's communication in the *BRITISH JOURNAL* nearly two years ago. (P. 904.)

In a paper before the London and Provincial Photographic Association, Mr. C. E. K. Mees described a method by which any desired degree of exaggeration of colour contrast might be introduced when copying a coloured original. (P. 911.)

Lead salts in self-toning emulsion for P.O.P. is claimed as a novelty at the Patent Office. Squeegees and plate-holders are among other patents of the week. (P. 913.)

Two cases of frauds by canvassers are reported this week under Commercial and Legal Intelligence." In one instance the offender was sentenced to two months' hard labour. (P. 917.)

We draw attention to the aid which the Press can give the public and photographers in repelling the attacks of fraudulent "free portrait" canvassers. (P. 903.)

The need of rapid production in Christmas trade is the subject of some notes from "Provincial Pro." (P. 909.)

Accompanying the reproduction of two photographs of Herr Ahnkoop's new studios we print some notes on the use of rooms other than the conventional studio for portraiture. (P. 907.)

The "largest photographer in the world" has expressed himself satisfied with the photographic portrait business in the hands of men who are ready to apply themselves to it. (P. 909.)

National Photographic Record Association. At the annual meeting on Wednesday an encouraging report of the spread of record work was presented. (P. 912.)

The winter reunion of the Photographic Convention of the United Kingdom is to be held on January 11. (P. 918.)

## EX CATHEDRA

### Society of Portrait Painters.

The New Gallery, Regent Street, which recently contained the fifty-first exhibition of the Royal Photographic Society, now holds the pictures of the sixteenth annual exhibition of the Society of Portrait Painters. The two shows are quite different in character, and those, particularly photographers, who visited the former will do well to pay a visit to the latter. In the former there were examples of pictures by our leading photographic portraitists, and in the latter pictures by our leading present portrait painters, among whom we may mention the names of Mr. J. S. Sargent, Sir Lawrence Alma-Tadema, Mr. Fanlin-Latour, J. J. Shannon, C. M. A. Orchardson, Thos. Hardy, and other present-day portrait painters. While the remembrance of the former is in mind it will be well to compare them with the latter. In the matter of posing the sitters, we think that our leading photographers have not very much to learn from the painters. It is more in the direction of lighting and background that photographers may profit. It is well known that painters pay as much attention to the background as they do to the portrait, and this is a point that the photographer, more especially the middle-class portraitist, appears to almost ignore. It is true that we do not see the glaring incongruities in backgrounds and accessories of a few decades ago; still, there are many to be met with at the present day amongst what may be termed second and third rate workers, who go in for scenic backgrounds. In many instances the sitters look as if they were stuck on to the background, or, indeed, let into it. Sometimes the lighting of the sitter and the background are not in accord. One very frequent defect in photographic portraits is that there is no atmosphere between the sitter and the background through his being placed so close to it. This is often necessitated by the shortness of the studio, but there is not always this excuse. The greater the distance between the sitter and the background the greater will be the atmosphere, and the greater the roundness and relief in the portrait. The portraits at the New Gallery should be particularly studied in this direction.

\* \* \*

### Popularity of the Picture Postcard.

Some idea may be formed of the increasing use made of postcards from a statistical abstract for the United Kingdom which has recently been issued. From this it appears that in 1891-2—that was before the picture postcard was popularised in this country—the number was something over two hundred and forty millions; last year it was over eight hundred millions. It is very questionable if postcards for general correspondence are much more used now than they were a dozen or so years ago. Therefore,

the extraordinary increase in the numbers may fairly be attributed to the picture cards, which now almost amount to a craze. There is no doubt that they have greatly increased the work of the Post Office, though not perhaps, proportionately, its revenue, for one or two picture cards with a few sentences on them are frequently made to take the place of a letter, particularly from persons travelling about. Be that as it may, the picture postcard has brought "grist to the mill" of a great number of photographers, and, possibly, the new regulation with regard to them, which we referred to last week, will bring still more. We are pleased to see that the vulgar, not to say indecent, things that were shown in some shop windows a year or two back, and which threatened to injure the business, have practically disappeared. Probably the exemplary punishments inflicted on the offenders has had the desired salutary effect.

#### Sketching in the Law Courts.

It will be remembered that some little while back the President of the Divorce Court, Sir Gorell Barnes, gave out that in future he would not permit the sketching of portraits of parties to the suits, or the witnesses in the cases, for the use of newspapers that make a sensational feature of such trials—snapshotting, as some of the daily papers termed it. These portraits—they can rarely be photographs—may possibly flatter the vanity of some, but to others they have caused much annoyance, to say nothing of inducing nervousness in a witness while giving evidence. It was for this reason that the President of the Divorce Court put his foot down upon it. Now each judge is the ruler of his own Court, and it was thought that, at a meeting of the judges some little time back, that others would follow the example set by Sir Gorell Barnes. But, according to the "Yorkshire Post," it will not be followed by his colleagues in the Chancery and King's Bench Divisions, or in the Bankruptcy and Referees Courts. On the other hand, should occasion arise by reason of special circumstances, each of the judges will be left absolute discretion as to issuing a similar order, for the time being, or in perpetuity. Thus it will be seen that, although sketching is prohibited in the Divorce Court, it is, for the present, freely permitted in all the others.

#### Local Restraint in Development.

The article by Herr R. Walter published in our issue of last week has brought us the letter from Mr. E. J. Mills, F.R.S., which appears on another page, and confirms the value of the method suggested. Our attention has also been drawn to a paragraph in the booklet "Paget Prize

Plates and How to Use Them," wherein the author, Mr. W. J. Wilson, notices the same phenomenon. To quote from the booklet:—"If two plates be treated in every way the same except that one is rocked during development and the other not, the difference between the resulting negative is surprising; the one which has not been rocked will be found poor and flat in comparison with the other. The reason of this is curious. The action of development releases bromine from the silver bromide of the plate, which bromine immediately combines with alkali, forming a bromide. Now this additional bromide, if not disturbed by rocking, remains in the developer at the place where formed, so that development at that part of the plate is additionally restrained. It will be easily seen that more bromide will be formed, and most restraining action occurs just at those places where action ought to be most vigorous and less in the less exposed parts; the latter will therefore develop more, and the former less, than they should, producing less contrast—i.e., flatness—in the resulting negative." The process in this paragraph is apparently regarded as of theoretical interest chiefly, and credit is due, we think, to Herr Walter for his advocacy of the system, in conjunction with the glycin developer, as a means of preventing undue harshness in negatives.

#### Impaired Light.

Though we are now in the middle of the month proverbial for its fogs, there has not yet been much to complain of as regards climatic conditions. The light has really been above the average for the time of year, and the temperature, too, above the normal for the season. Yet these conditions cannot be expected to prevail much longer, and, as it is, exposures in the studio have to be much longer than they were a month ago. That alone, however, is not a serious matter as the plates have developed much as usual by reason of the moderate temperature. The impaired light in conjunction with a greatly depressed temperature would, possibly, have brought trouble to some. Since last winter not a few, who practised photography as amateurs, have entered the ranks of professionals, either as assistants or in business on their own account. It is to these inexperienced ones that trouble may arise, and more through temperature than light. If the image is tardy in making its appearance, under-exposure is generally suspected by them, and a longer one is given, with the result that the negative is really over-exposed and lacks vigour in the end, the slow appearance of the image being due entirely to the coldness of the developer. These conditions are perfectly understood by all experienced workers, and fully realised by them.

### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1907.

Edited by GEORGE E. BROWN, F.I.C.

The forty-sixth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached the total of 1,616 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1907 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### THREE-COLOUR PHOTOGRAPHIC PRINTING PROCESSES,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1907 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1907 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—Our publishers ask us to inform Agents that it will be as well to place their orders for copies immediately, as the issue is always booked before publication, and a second edition will not be printed.

this time of year. It is only with the novice that the trouble arises, as he does not recognise the effect that temperature has upon development, and in obtaining density in his negatives.

**Depressed temperature.** Again, some amateurs may still have undeveloped plates left over from their holiday tour, and, when development is commenced, underexposure may be imagined and the negatives treated as such, while, as a matter of fact, they are fully exposed. It is universally known, or should be known, that the best temperature for development, both for the developer and the room, is from 60 to 65 deg. Fahr., and anything less than that should be taken into consideration in the operations, and longer time allowed. There is another point that novices should take into account, namely, that all chemical actions are slow in a depressed temperature. Therefore, a longer time in the hypo bath should be allowed for both negatives and prints, if yellow stains are to be avoided, than is necessary when the temperature is normal. Furthermore, very cold water has not the same solvent action as warmer; therefore a longer washing is necessary in order to ensure the entire removal of the last traces of the hypo. We are led to these remarks because, in previous years, we have had so many inquiries from correspondents, professional as well as amateur, as to the cause of yellow stains on prints, which have been entirely due to too short a time in the fixing bath for the temperature at which it was employed.

**The interior of the camera.** At the present time of the year the difficulty of getting fog-free negatives is one that frequently confronts the studio worker. The haziness of the atmosphere penetrates the building, and even the efficient heating of a room is not always effective as a method of keeping it fogless. Negatives taken under slightly foggy conditions may be made to give brilliant prints if a fairly strong and well-restrained developer be used and development prolonged; but, as such negatives are slow printers, such a method of working is hardly practicable where daylight printing processes are used. The operator must, therefore, see that there are no other contributory causes of fog. The plates used should be particularly clean-working and of good latitude. The black-room window should be renewed and carefully tested to make sure that no fogging is occurring there. The lens should be carefully examined, the glasses cleaned with a piece of well-washed silk slightly moistened with alcohol, and any bright edges on the brasswork inside painted with dead black. The condition of the inside of the camera is as likely as not helping very greatly to produce foggy plates. While grey dust settles on some of the inside surfaces and promotes reflection, or if the inside is frequently dusted the surfaces are rubbed more or less smooth and bright. All these surfaces should be carefully packed, some drop black mixed with negative varnish answering fairly well as a dead-black paint. As a further precaution a cardboard diaphragm may be cut, having, of course, a square opening large enough to avoid obstructing either upright or oblong pictures, and this may be fixed in the folds of the bellows about two-thirds of the way between lens and plate and nearer the plate. Such a diaphragm is better covered with black velvet than painted black.

**Society programmes.** In reference to our note on the non-photographic fixtures which enter largely into a number of society programmes, Mr. Gordon R. Lynch, junior, the honorary secretary of the West London Photographic Society, writes us as follows:—"I should like to point out that the programme of the West London

Photographic Society is almost entirely given up to the technical side of photography, and contains for the current session such subjects as emulsion making, home-sensitised paper, enlarging, ozobrome, systematised exposure, and photo-micrography. All these subjects are being given by our own members, and in no case do we have outside help. Only one meeting this year is given up to the artistic side—i.e., the after treatment of the negative for pictorial purposes—and in this it is intended to deal with the practical side as much as possible." Mr. Lynch misunderstands our comments if he assumes them to deprecate the discussion of art subjects in a photographic society. Such was not our intention, for we would be glad to see a greater interest in true art subjects among photographers, and we can imagine no more suitable occasions for educative talks on art subjects than the meetings of photographic societies. Our protest was directed against the purely "entertainment" lecture of travel or industry, the tendency of which, we believe, is to weaken a society from the photographic standpoint, even though members may thus be added to the membership roll. Numbers, however, are not a sound criterion of a society's strength.

#### CANVASSING FRAUDS.

"I SHALL never employ a canvasser again." The remark, made to us by a prosperous photographer whose customers are chiefly of the lower middle classes, is indicative of the disastrous effects of the fraudulent canvasser upon photographic businesses of this description. And not upon those of this class only, but, by the indirect lowering of prestige, upon the whole photographic profession. We suppose there is scarcely a town of any importance in these islands where the unscrupulous methods of the canvasser has not made a bad name for photographers, by associating them with a gang of sharpers who trade upon the ignorance and gullibility of a large and poor section of the public. The magic catch-word, "something for nothing," has only to be shouted, and a procession of ignorant persons come walking into the canvasser's net. We have exposed the proceedings of these gentry so often that none of our readers can be unfamiliar with their methods; and many know of them to their cost. And yet neither we nor anyone else have been able to prescribe a formula which would protect photographers and the public from the insidious attacks of men who are no better than thieves, and only a stage or two removed from blackmailers. Prompt advertisement of the system on which the canvassing trade is done has had the satisfactory result of moving the gang on to places where photographers are less keenly on the defensive, but even then a good deal of damage has been done. Some time ago we called attention to the valuable aid which local newspapers can render in enlightening their public as to the true character of the trade. One or two papers, we are glad to say, have shown their public spirit by calling attention to the fraudulent basis of the canvasser's offer of a free enlargement, and to them we must now add the "Perth Constitution," which has taken up the cudgels in the interests of the public and of photographers in its district. As its articles on the subject may be of service at any moment to those of our readers who find themselves attacked by the travelling canvasser, we quote them from our contemporary's issues of November 5 and 7:—

"Complaints have reached us that Perth is at present being visited by photographic canvassers, whose method of doing business is alleged to be misleading. It is said that they are making calls on behalf of an unknown Art Photo Company, said to be contemplating starting busi-

ness in the city, and, purely for the purpose of advertisement, they ask for photographs for enlargement, which will be carried out free of charge. The offer is tempting, and many housewives are said to have taken advantage of it. The photograph secured, the canvasser, a very persuasive and genial individual, takes his departure elated at his success, and after a lapse of a week or two returns to inform the housewife that the photograph has been enlarged. The enlargement is exhibited, and the lady of the house is informed that she can have it for 15s. Naturally the housewife remonstrates, and reminds the canvasser that the photograph was to be free of charge, whereupon she is informed that the price is only a charge for the frame, and that the enlargement is a gift. The other day a housewife refused to pay the sum, and demanded the original photograph. This was refused, and it was only when proceedings were threatened by the husband that the photograph was returned. It is alleged, however, that a number of people have not been so fortunate, and two families in the city are said to have lost half-a-dozen photographs between them. Now that attention has been called to the matter, no doubt housewives will be placed on their guard."

"The announcement made by us on Monday regarding the individuals who are engaged in the city canvassing for photographic enlargements has caused quite a sensation in some districts, as it appears that the individuals engaged in this work have made a pretty systematic canvass in particular districts of the city, and so far as obtaining original photographs for the purpose of enlargement is concerned, they have met with considerable success, although they appear in some instances, at all events, to have found it very difficult, if not impossible, to get people afterwards to pay a sum for the frame. In many instances those concerned have also found it equally

impossible to obtain a return of the original photograph. One of the reasons given by canvassers for this method of doing business is that they intend starting business in Perth, that they are on the look out for suitable premises in a leading thoroughfare, and that they have adopted a plan of giving free enlargements of photographs as a novel means of advertising. The other day a party who had given a photograph, and been promised the free enlargement by yesterday, wrote demanding back the original photograph, and this morning received the following reply:—"Dear Sir,—In reply to yours, our representative will call on you some day this week and submit proof. Hoping this will suit you." The proof-submitting stage is the time when the happy housewife desirous of bargains finds that all is not gold that glitters, and that she only receives the free enlargement on condition she pays 14s. or 15s. for a frame."

This article is headed "A Warning to Householders" and is given a prominent position among other news. Its clear exposure of the clever ruse on which the canvassers depend for their trade should open the eyes even of those who have not heard of Monsieur Tanqueray and his similar amiable philanthropic designs conveyed through the post. We suggest that every photographer, soon as his district is assailed by the canvassing fraud, should take steps to convince his local newspapers of the real character of the business, and such is our confidence in the Press of this country, that we venture to offer the assurance that an appeal for fair play will never be made in vain.

We commenced by quoting the resolution of a photographer never again to employ canvassing in his business. We imagine that every professional photographer who values his business status must inevitably and immediately come to the same decision.

## PHOTOGRAPHY IN COLOURS BY PRISMATIC DISPERSION.

THE following article is from the current issue of the paper devoted to colour photography recently founded by M. Chas. Mendel, at 118, Rue d'Assas, Paris, under the title of "La Photographie de Couleurs." We are indebted to M. Mendel for the use of the illustrations.—EDS., B. J. P.

IN the first number of January,<sup>1</sup> 1904, of THE BRITISH JOURNAL OF PHOTOGRAPHY, Dr. Julius Rheinberg explained the principles of a process of photography in natural colours by spectral prismatic dispersion. This communication, unfortunately, was not published in France, which explains the fact that researches were undertaken on a similar process, the priority of which is still to be claimed.

I have had for some years the idea of using the phenomenon of dispersion, and of using the prism, that marvellous instrument of the analysis of colour, for a new method of photochromy. Having been able, last February, to complete some conclusive experiments, I took out on March 23 of this year a patent for an apparatus based on this principle.

According to a recent number of the "Photo-Revue," M. Raymond, although employing another arrangement, appears to have worked on the same lines. Finally, M. Gabriel Lippmann, to whom is due the discovery of the beautiful interferential method, and who was ignorant of this patent and of Dr. Rheinberg's article, made a communication on July 30,<sup>2</sup> to the Académie des Sciences on an identical process of photography in colours.

There are at the present time, properly speaking, two known

processes for obtaining photographs in colours, the interferential method of M. Lippmann, and the three-colour process in its various applications.

The interference method, which still remains without doubt the most beautiful and the most scientific of all, because it enables one to register the actual vibrations of light, presents unfortunately in practice so many difficulties as to dishearten amateurs, and especially on account of the long exposures that are necessary.

Trichromy, on the other hand, is based on an analysis of colours that is quite arbitrary, for it requires the use of selective screens of artificial tints. On the other hand, it also leads to long and complicated manipulations, which constitute a serious obstacle to its development and popularity.

That which is particularly attractive in the process of prismatic dispersion, is that one is working entirely without scientific analysis of colour, based on a physical principle which is absolutely constant; there is no necessity (apart from a somewhat longer exposure and the use of more cumbersome apparatus), for any operation more difficult than that of taking and printing an ordinary photograph. It presents at the same time the advantage of giving absolutely pure colours, for there does not enter into their composition the slightest atom of pigmentary dyeing, and the colouration of the image

<sup>1</sup> "B. J. P." January, 1904, p. .

<sup>2</sup> B. J. Aug. 17, 1906. p. 644.

only to the play of light passing through a ruled screen and a prism, both transparent and colourless.

No serious apparatus has yet been constructed for the practice of this process, so far as we know—it is true we have only laboratory experiences—but the principles are the same whatever may be the apparatus employed, and the manipulation will be still simpler if suitable apparatus is at hand.

Everyone knows the result of allowing a ray of white light to fall upon a prism and of receiving upon a screen the image (spectrum) formed by the dispersion of the simple colours contained in the ray; each of the colours being diverted at a different angle, which is a constant for the same incidence. Supposing, now, that we replace the screen E, Fig. 1, by a photographic plate, and that we wish to obtain a record having the power to reproduce the colour of the ray which has acted on it. If the incident ray, A B, is green, for example, it will be deviated in passing through the prism P according to the angle of refraction of the colour (green), and will act on the plate at a point situated on B O. Suppose that, after having developed this plate and printed a transparency, we replace it exactly in the place occupied by the negative.

Fig. 1.

Now we let a ray of white light fall on the prism following the same incidence as the ray A B, the simple colours contained in this ray will be dispersed by the prism, and will form on the transparency a complete spectrum. But for the observer seated at O, this spectrum will be masked by the opacity of the plate, except, however, at those points which, being impressed on the negative, will alone be transparent on the positive, and will allow naturally a green ray to pass; since, as stated above, it will correspond to the deviation of the green ray contained in the incident ray A B. We shall have thus obtained the reproduction, with its exact colour of a ray issuing from a given point by a very simple photographic process. An image being composed of an infinite number of points, it is easy to see that if the operation gives everywhere the points of the image, we shall be able to reproduce it with all its colours.

However, the process is more complicated in practice, and I confess that I was some years in finding the second element which, combined with the prism, enabled me to obtain the desired result.

I could obviously not think of photographing at once all the points of the image, for each point giving a spectrum that enlarged, the latter would be superimposed on the spectra of the neighbouring points, and the result would be merely a bluishness on the edges of the image. The idea occurred to me to photograph successively, in a kind of cinematograph apparatus, a series of luminous slices of the image, which could be then dispersed by passage through the prism and projected on a plate in the form of a disc, which should be in rotation. But the fatal vibrations which are produced by a cinematograph apparatus would cause a mixture of the colours, and would render any result impossible, and I gave up the experiment, to follow my researches in another direction. Finally I had the idea of dividing the image into an infinite number of lines separated by opaque bands. Each line would

then act as an independent source of light which, photographed by a lens placed in front of a prism, would form a spectrum in the interval left by the spectrum of the neighbouring lines.

I then obtained a screen ruled with opaque lines of 5-30 mm., separated by a transparent space of 1-30 mm. It was actually necessary to have a space as large as possible between the breadth of the transparent lines which should act as luminous sources, and that of the opaque lines on which are extended the spectra on the photographic plate, if one desires the colours to be well separated.

On the other hand, it is not possible to increase indefinitely the breadth of the opaque lines without running the risk of absorbing too much light and consequently increasing out of all proportions the duration of exposure. The ratio of 1 to 5 appears to me to be the mean between these two considerations, and it has given me sufficiently satisfactory results. Unfortunately, such special screens as those which I required are necessarily difficult to make, and after having waited several months for mine, and then not having had them delivered, I thought of making some myself which, though somewhat coarse, would serve in place of better ones.

I do not believe that it is altogether uninteresting to mention here the first results at which I thus arrived, for everyone knowing slightly the photographic manipulations, and desirous of repeating the experiment, will certainly be able to obtain similar results; the only apparatus necessary being a bellows camera, a box of panchromatic plates, a compensating filter, and a prism of 12 degrees, which can be obtained of any optician.

Fig. 2.

M, mirror; D, ground glass; V, green glass; R, red glass; P, prism; S, cliché; L, magnifying glass.

Here, then, is how I set to work: I obtained a mirror about 20 by 30 cm.; I made marks at every 5 mm. on the two small sides, and with a ruled plate and with a jeweller's screwdriver 1 mm. wide I scratched the mirror with a series of lines which formed the transparent spaces of the screen. These transparent lines, 1 mm. wide, were separated the one from the other by opaque lines 4 mm. wide, formed by the intact parts of the mirror. Obviously, I could not hope to form by means of the first lens the image of an object on such a rudimentary screen, but I could nevertheless photograph flat and transparent objects, such as pieces of glass, by applying them to the mirror. I commenced with very simple experiments. I fixed the mirror, quite vertical, on a horizontal board, and I affixed to the ruled side two squares of glass, a red one at the top, a green one at the bottom, with a white one in between (Fig. 2).

I placed my prism, of about 12 degrees, with the refracting edge vertical and parallel to the lines of the mirror, on a small wooden support, which could be revolved on its axis, in front of the lens of an ordinary 9 by 12 cm. camera, and I fastened this chamber at the other end of the board, after having turned the prism support so that the prism was at its angle of minimum deviation, a condition that is essential to obtain sharp spectra. Finally, I calculated the distance and the focus, so that the spectra given by the transparent lines of my mirror were exactly side by side without overlapping one on the other. Naturally, I placed the reflecting side of the mirror away from the lens, with a sheet of ground glass

in contact with it, and I placed the board so that daylight passed through the lines on the mirror. I then examined, by means of an eyepiece, the image thus formed, before taking the photograph, and I found that the rays from the central part of the mirror, illuminated by white light, gave me perfect spectra, and that, on the other hand, at the top of the mirror, and consequently at the bottom of the photographic image, the

the upper part of the green glass, and the image is to so extent vignetted.

Perceiving that I was on the right road, I aimed at photographing a more interesting subject, and cut out of paper a gelatine a reddish iris, a green stalk and leaf, a yellow leaf and a blue fly. I mounted these on a ground glass, and placed the whole against the ruled mirror, after having operated

Fig. 3.

rays illuminated by red glass were deviated to the left by the prolongation of the reds of the complete spectra, whilst at the base of the mirror, that is to say, at the top of the image, the rays illuminated by the green light, corresponding to a region rather more central, were in a prolongation of the green of the complete spectra.

Then I took a negative of this image, and printed a positive and replaced this as exactly as possible in the place which the negative occupied in the apparatus, removing, of course, the coloured glasses from the mirror. Finally, I fitted a magnifying glass of a diameter almost equal to the photographic image, at the back of the apparatus, against the positive, so as to increase the visual angle, and on placing the eye at the focus of this lens, I perceived an image composed of three bands superposed. At the top was a green band formed by a series of green lines, in the middle a white band formed by a series of complete spectra, and at the bottom a red band formed by a series of red lines. The result was easy to foresee, for the transparent parts of the positive were substituted for the parts impressed on the negative, and only passed those rays which had undergone, through the prism, the same deviation, that is to say, those rays of the same colour. Naturally, the replacement of positive for negative plate ought to be perfect, for if the image of the positive is not exactly substituted at the place where the image was formed on the negative, the colours change—the red, for example, becoming green, the green yellow, and so on.

Fig. 3 is a reproduction of one of the first records obtained with this arrangement; only, as I used artificial light for taking the negative, the result was irregular illumination in

Fig. 6.

Fig. 4.

exactly as before. Using a panchromatic plate and a compensating filter, I obtained the positive, reproduced in Fig. 4, which, when placed in the apparatus, gave me actually a satisfactory result. The displacement of the lines of the image resulting from the dispersion of the different colours through the prism is still easily seen in this proof.

Fig. 5.

T, screen; V, micrometer screen; P, prism; S, cliché; L, magnifying glass.

Immediately after these experiments, I received the screen for which I had waited for such a long time, and which enabled me to follow up my experiments in a more perfect and more conclusive fashion.

I was not now obliged to take the photographs in a normal way. I had been obliged to use flat and transparent subjects so that I could place them directly on my mirror, the enormous lines on which appeared on the positive as villainous bars which gave a very bad effect.

With a screen of 1.5 mm. I was able, on the contrary, to combine two cameras—Fig. 5—the first intended to form on the screen, by means of the first lens, the image of the object to be photographed, which might be anything, either opaque or in relief; the second intended to re-take this image

lines by a second lens (in front or behind which is the prism), and to project it on a photographic plate in a series of spectra side by side. Naturally, the lines of the screen are very close together; the angle of the prism was much reduced (2 degrees 40 minutes). Under these conditions focussing was effected by means of a micrometer screw, which shifted the screen minute distances to the right or left. Two magnifying glasses were employed, and were absolutely necessary, the one behind the screen to make the rays converge towards the second lens, the other behind the second lens to converge the rays striking the positive, to the observer's eye.

Fig. 6 is a reproduction of the best positive that I have yet obtained with this combination.<sup>3</sup> The bouquet is composed of a green fern leaf, a violet iris, a white convolvulus with greenish centre, three yellow marguerites, and two cornflowers, then an orange to complete the subject. All the flowers are well seen in their respective colours. The orange alone, which is on the margin of the image, had suffered, doubtless the effect of optical aberration, and persistently appeared violet! As this process is still in its infancy, and will doubtless make the subject of criticism, it may not be out of place to reply to those now.

One reproach is that it is necessary to use an apparatus to examine the positive in colours; the positive, seen in the hand, is nothing more than an ordinary black and white

<sup>3</sup> The image loses sadly much of its interest through the crosslined screen used in making the blocks. But one can still see the lines of the screen used by the artists.

photograph. I do not consider that this criticism is really formidable, considering the increasing success of the stereoscope.

Then, having accepted the necessity of using a stereoscope to see an image in relief, there is much more reason to resign oneself to the use of an analogous apparatus, when it enables one to see the subject in relief and in colours at the same time. Recognising, once for all, that there is still a little further complication, as the result of the use of the micrometer screw for focussing.

A more scientific criticism is that the photograph obtained by this process is not an exact reproduction of the object photographed, the image undergoing an alteration in consequence of its division into a number of lines, and a deformation in consequence of its passing through the prism. This criticism will always be mathematically exact, but one may reply that the certainty of further diminishing the separation and the thickness of the lines will render the latter quite invisible. As regards the distortion resulting from the passage through the prism, it diminishes in proportion to the separation of the lines, the angle of the prism being naturally reduced as the lines become nearer to one another. With a prism of 2 degrees 30 minutes, this distortion is quite imperceptible.

Finally, a criticism based on practical grounds reproaches this process with the necessity of using a double apparatus, and consequently of being very cumbersome. This is undoubtedly a great objection, but I do not believe it is insurmountable, and I shall perhaps return to it again.

ANDRÉ CHERON.

## THE ORDINARY ROOM AS THE PROFESSIONAL STUDIO.

More than ordinary interest attaches to the opening of the new establishment of Herr R. Dührkoop in the largest block in the leading thoroughfare of Hamburg, because the rooms in which Herr Dührkoop has elected to carry out his photographic portraiture, and which he has most handsomely decorated for this purpose, are not provided with the illumination which is usual in photographers' studios. Except that their size and furnishing are specially directed to the purpose of the apartments, the latter are ordinary rooms. They are not supplied with a top-light as a studio is, and they are innocent of the time-worn accessories which still survive in many establishments. By courtesy of Herr Dührkoop we give views of two of these studios, from which an idea will be obtained of the original nature and thought expended on the decoration and fittings. The main character of the rooms may appear somewhat loud to English thinking, but the German mind tolerates a more lavish use of ornament in public and domestic apartments, and the plainness of a room furnished on reserved English lines would doubtless impress Herr Dührkoop's clients as poor, however much money it had cost to produce the effect pleasing to British eyes. The chief interest, however, of the new establishment lies in the fact that in these rooms, deprived of the facilities of the average studio, Herr Dührkoop has settled down to produce the portraiture which is familiar to our readers who saw it at our offices in the spring, or have since seen it at one or other of the exhibitions in the country. In making this move, Herr Dührkoop, we have no doubt, does not claim to be the originator of a new idea. He is a man of wide interests, and probably has studied, through the Press, the success of Mr. W. Crooke in Edinburgh, whose studio is arranged on lines which give him facilities of the kind which Herr Dührkoop has deemed sufficient. Mr. Ralston, in Glasgow, also, has found the sufficiency of a side-light studio

for the most varied requirements of professional work, and other examples could be cited. Yet we doubt if there is a photographer who, in expending large sums of money in installing himself in a new place, designedly elects to work in a studio which is such a wide departure from conventional

A Studio-room in Herr R. Dührkoop's new establishment in Hamburg.

models. That Herr Dührkoop's experience has led him to take the step should encourage other photographers to inquire whether they may not employ their own premises more advantageously. Magnesium light is used by Herr Dührkoop extensively in his business, though we believe we are correct in

assuming that in his new studio he does not rely on artificial light even as an auxiliary in ordinary portraiture.

The German papers, in noticing Herr Dührkoop's new enterprise, mention the numerous awards and medals which have fallen to him of recent years, including the gold medal at the recent art exhibition at Dresden. We may also refer in this

Nowhere in this brochure is there a word about prices—though Herr Dührkoop has a fixed tariff, and does not adopt the Gilbertian policy of making the punishment fit the crime according to the means of his customer. There is not a word in it about "art photographer." Nothing, indeed, in the way of personal beating the drum, but a fair amount of editorial

Herr R. Dührkoop's new premises in Hamburg.—A reception-room.

connection to the book published by Herr Dührkoop and issued to the public in Hamburg about the present time. It is a volume containing the announcement of the new premises and extracts from the Press references to his portraiture, including those made on the occasion of the exhibition of his photographs at the BRITISH JOURNAL offices. It also contains reproductions of about a dozen portraits, simply inserted without comment as "Professor-So-and-So," or "Geh. Regierungsrat Hoffman."

**PHOTOGRAPHS as Presents.**—Messrs. Pearce and Co., of St. George's Press, Brentford, write:—"We have read with interest the article in last week's issue, entitled "Letter to a Middle-class Professional." The idea of photographs being used as presents is one that we have been doing a lot of business with this season, in the form of the enclosed booklet, which we have supplied to photographers in all parts of the country. Some have had it illustrated with half-tones of their different lines, while others have incorporated a brief price list. We think that many of your readers will be glad to know that the advice given to them in the article can thus be easily followed, the only respect in which we feel inclined to differ from your correspondent being that of having to wait until next spring for an adequate reward for the outlay." The booklet sent by Messrs. Pearce is a very nice example of effective typography and two-colour printing.

licence in the way of granting space to others who are prepared and glad to perform this necessary task. In short, while Herr Dührkoop is acknowledged in this country as a photographer of a strong and refined individuality in his work, an examination of his business methods shows him to be an astute man, having the instinct of saying the right thing in the right way and devoting his talents in this direction towards the necessary end of drawing people towards his studio.

**WITH** the forthcoming December number that successful magazine, "The World's Work," which has dealt instructively with photography in its pages, proposes to celebrate its fifth birthday and the beginning of a new volume, with all manner of novel features, and with a general broadening of its unique scheme. The pressure of public and other work has caused Sir Henry Norman, M.P., to relinquish the editorship, and with his departure the magazine will abandon all partisan politics. Mr. Heinemann, the publisher promises that the magazine shall devote itself quite independently to interpreting the progress and recording the manifold activities of the world which works, of men and women who do things, of nations as well as industries in the making, with beautiful pictures which will mirror the time and the wide opportunities throughout the Empire which to-day await the enterprising Briton.

## MORE LETTERS TO A MIDDLE-CLASS PROFESSIONAL.

DEAR J.—In my last letter, mentioning Christmas work, I had space to deal with quick production.

By quick production I do not necessarily mean the use of artificial light paper. I mean rather the rapid turning out of the ordinary work of the studio. A little organisation and common-sense arrangement of batches of work frequently results in great saving of time. You should immediately examine your method of working, see if the various steps can or cannot be made less steep, or even steps cut altogether. Often habit and use have sanctioned arrangements that have been out of date since some improvement in your premises, increase in hands, or change of process.

Much can be done by rapid drying of negatives and quickness of fixing. As an instance, I will describe the procedure when an order for an enlargement was required that had to be begun and finished same day. At ten o'clock a bromide transparency was made in contact, developed, and fixed. Washing was conducted by suspending the transparency on an old pyro bottle, immediately under a running at top pressure. Ten minutes was considered sufficient, as the film received clean water every second in place of soaking in hypo-tainted water. The plate was now dried on both sides with a fluffless cloth and placed within a yard of a slow combustion stove. A warm air dried the film in half an hour, and we prefer the plan of methylated spirits, as the latter sometimes gives a milky sediment, makes tears.

When dry the transparency was covered with tracing paper, and the latter worked upon. Also hair was put in, hair darkened, nose and mouth altered, and wholesale improvements generally made upon it. (N.B.—The enlargement was for exhibition purposes, and was to resemble closely a famous picture.)

Four enlargements on dry plates were now made from the worked-transparency. These were treated in an exactly similar fashion to the transparency, and were put on to print in platinotype at two o'clock in the afternoon.

Platinotype is quicker than carbon, P.O.P., or even bromide, when good prints are wanted quickly, for the fixing and washing are not, and the print has the advantage of not deteriorating when dried by artificial heat. Our prints were dried for cutting out in ten minutes, mounted, and again dried by the fire, and were detached by the evening mail.

This method, however, can hardly be used when a quantity of prints are to be made within a day or so and artificial light papers must be used. At one time only bromide paper was possible; now either gaslight or bromide has to be decided upon. If you are not in the habit of using either I should advise you not to leave the matter until the last minute. No one can expect to make perfect

prints on either paper straight away, and bad prints on bromide or slow contact paper are very bad indeed.

Bromide paper in particular, though capable in the right hands and with the right negative of making prints every whit equal to platinotype, is more likely in inexperienced hands to give harsh or badly-coloured prints.

Gaslight paper, since it requires a longer exposure than bromide, has been rather neglected by the professional worker, though it has many points in its favour.

The appearance of a good gaslight print is far softer and more full of velvety rich shadows than the quicker variety. The surface of many of these papers closely resembles collodio-chloride matte, and takes far better with the public than does the ordinary bromide. There is rather more latitude in exposure also. Be sure, however, that your developing formula is compounded exactly to the maker's directions. I know several photographers who have given the slow paper a bad name because they have used their ordinary bromide paper formula. The quantity of bromide of potassium should not be a matter of guesswork, but must be measured most carefully, otherwise fog or greenish prints will probably appear.

For printing on these slow papers we proceed as with daylight, arranging several frames round the illuminant together, thus making the question of long exposure of no consequence. The developing tray is screened off from the printing light by a large piece of canary fabric. No great care need be exercised in fixing this up, but it is better to develop by this light, since there is no need for the care otherwise requisite to avoid fog.

The one great drawback of gaslight papers has, in the past, been the need for very thin negatives useful for no other process.

Now, however, there is a brand on the market which gives more beautiful soft prints equalled by none except carbon or collodio-chloride from the regulation dense carbon negative.

We see that we have given the ordinary bromide paper most recognition. This, however, is only because the gaslight variety has been misunderstood by the profession, and not because of any unsuitability of the rapid bromide.

When the printer is in the habit of using artificial light for printing year in and year out, and does not only take it up for a week or so, it is, without doubt, more suitable than the slow variety, for negatives and working are naturally arranged to suit its peculiarities.

Great care should be exercised in the drying of prints at this season; slightly damp prints placed together so that the air cannot dry them will in all probability develop some defects.—Yours,

PROVINCIAL PRO.

## THE EXPERIENCE OF THE LARGEST PHOTOGRAPHER.

THE following confession of faith (and hope) in the photographic profession is made by one whose claim to be the largest photographer rests upon the unassailable grounds of the physical dimensions of: Height 6 ft. 7 in., and weight 340 lb. For the breezy expression of the writer's optimism we are indebted to our New York contemporary, "The Photographer."

Much has been said in the past five years by the fraternity about their business being a failure that I naturally am a trifle doubtful about approaching the subject and making any claims to success, but, feeling sure that not all the craft are getting such meagre as they should out of it, I gladly accept an invitation from a friend to talk a little on the subject.

Photographers as a rule are all kindly dispositioned and willing to accept from a brother any advice which may be of benefit to him, so draw near while we have a little heart-to-heart talk upon a subject which lies nearest my heart.

Thirty-five years behind the gun doing business in thirteen different cities and villages, working for all classes of people, has naturally opened my eyes as to the proper methods to successfully conduct a photographic studio. I have always showed in small towns, 12,000 inhabitants being my largest. I learned all branches of the business so far as I was able, so I have been my own operator, developer, printer, finisher, and office boy, consequently I have put

in a great deal of overtime; in fact, made such hours as my business required for the faithful performance of it, many mornings reaching my studio at 3 a.m. My time has been fully occupied always, with no time to grumble or complain about business, or to wish that the sun had never shone the morning I took up photography as a livelihood. Starting in life with scarcely a dollar, I owe all I am financially to Rotten Photography (as many call it), and no stock house ever had a dollar's claim to my studio and no stock dealer ever settled my bill by taking less than a hundred cents on a dollar, and my one great ambition in life has been to keep my faith and credit good with all. My studios have made money from the start, and I am making it to-day and doing all my own work, or greater part of it. I am located in the beautiful village of Lebanon, N. H., which was never considered much by anyone as a field for photography—but let us see about it.

I opened my studio for business August 1, 1905, with two other studios in the village and other in near and adjoining towns, and

the prices of work were from 25 cents a dozen to anything that could be had. I put in a good line of card stock and opened at \$4.00, \$5.00, and \$6.00 a dozen, according to mounts and finish. Crayon portraits (so-called) were given with trade at stores and also made and framed by local artists and agents canvassing from door to door at from \$1.75 to anything they could get. What happened? And why do I to-day hurrah for portraiture? I am getting same prices as when I started. My business has increased to such an extent that lately I have been obliged to send a part of my retouching away, and looking over my books October 1, 1906, I find I have made 1,000 negatives, 61 (sixty-one) 16 x 20 and 20 x 24 portraits, and thirty-six (36) plain enlargements, the portraits ranging in price from \$10 to \$35 apiece, consequently I figure a nice little profit on fifteen months' business. Handy thing to have, this profit. Now then, do I hear you say, "Oh, well, Lebanon, N. H., is an exception"? If so, I ask you why? Do not people want portraits in other places as well as here? Most assuredly they do, and yet to-day there are hundreds of places of this size with studios who do not average six life portraits a year, and where the travelling salesmen are met with the report that business is rotten. But I say it is the man, not the business.

Failure to get a dollar to-day out of photography cannot be laid at the door of the art but rather to the methods under which it is conducted. I care not what you may say in regard to your neighbour having a better light or better appointed studio. I say good work can be made under any light if it is intelligently understood, even by a common window, and I call to mind to-day a young man with no advantages who served an apprenticeship with me and then opened business in a town of not over 1,000 population and in a room 8 x 15, and only one room at that. Buffed his paper before silvering on the floor and made his work all by a side window, yet made his first dollar and got his start in life in such quarters, and his stock dealer told me himself that he was as good as gold, and his name good for anything he wanted, and to-day he is a prosperous artist in New York State with a good bank account and doing good business—and good work, too.

You who grumble, is it the profession or the man in the profession?

There are several reasons why we fail. We talk too much, we cheapen our productions in the mind of the public by trying to cut

prices down to nothing simply to do the other fellow and get down ourselves.

Strive to educate the public as to what constitutes good work, have a certain amount of dignity under the light, and give people to understand that you have made a life study of faces and that they should place themselves entirely in your hands for the best results, and then be never satisfied with your work or think for a moment you have reached the last round in the ladder. Never grumble at resittings, but carry a cheerful air into the reception room. No matter what the conditions, make the patrons feel you are perfectly willing to try again, and the results will be even an astonishment to yourself. Above all things, never let a patron go away dissatisfied, no matter what the sacrifice is to you. Contrive in some way to get the people with you. It is the secret of success. Above all things, keep in touch with late mountings and styles. Use good goods, do good work, and get good prices. Risk a little something in the line of large work. No matter if they call you "the man who dares." Get up nice portraits of your patrons with their permission, in sepia, colour, or pastel. Place them on exhibition, show to the public that you mean business, and I guarantee if you do well you will have none of them left on your hands after Christmas, but all this must be done in a business way.

Try to educate the people to know that the time of a natural artist is valuable, and portraits with merit in them cannot be made for nothing. Appeal to their good taste and judgment, have better qualities of work on hand, point out the difference between the good and the poor, use a little diplomacy on your part, and it will scarcely ever fail to win them over to the best work and unlock the strings of their pocket-books, and one No. 1 job out of your studio is worth more to you than a dozen cheap ones. But if you are incompetent and not adapted to handle the public and make success of photography, get out of it and give way to some one who has business methods at his fingers' ends. Don't for ever ride on the rear end of the train and grumble because you can't pay your bills or make a dollar at your profession, for the public will soon see the point and have no respect for you, or your business either.

If this talk shall be the means of producing a hustle on a grumbler and accomplish the mission upon which it is sent, then I am content.

W. H. SWAN.

## THREE - COLOUR PHOTOGRAPHY.

(Abstract of Lecture by Mr. A. J. Newton, at the Croydon Camera Club, on the 7th inst.)

THE Croydon Camera Club is fortunate in having so many friends and members willing and capable of giving first-class lectures and demonstrations. It need hardly be said that when Mr. A. J. Newton is conversing about three-colour work he is talking about a subject with which he is thoroughly acquainted in all its bearings, and, in addition, he has the capacity of expressing himself in terms which are readily understood by all.

### General Principles.

The principles underlying "colour," Mr. Newton said, apply equally when copying pictures, as in direct work. Light is purely a subjective phenomenon, and must therefore be considered in relation to the apparatus of vision. The composite nature of white light can be demonstrated by means of a prism, and the almost universally accepted theory is to consider it as composed of a series of complex undulations, or waves in the aether, each differing in length, "wave length" being the distance from crest to crest. This is adopted as the basis and method for calibrating, or mapping out the spectrum. The unit adopted by Angström of wave-length is the "tenth metre," equal to 1-10,000,000 millimetre. Red, for instance, has a wave length of 7,000 A.U.; violet 4,000; each colour having its own particular wave length, by which it can be identified. Substances appeared coloured merely owing to the composite nature of white light, which suffers partial absorption by a coloured substance; the mixed remainder is reflected back, and creates the visual impression of colour.

### Method of Recording Colour.

The procedure of taking an ordinary monochromatic photograph may be regarded as recording "white" by "black," and then printing in minus black—viz., white. Similarly, one can represent "red" by recording this colour, and printing as minus "blue and green," viz., "red." Clerk-Maxwell showed that all colours could be imitated by a mixture of three colours, a certain red, green, and blue-violet, and Mr. Newton pointed out that this might be independent of the fact that the machinery of vision was supposed to have only three sets of different colour-sensitive nerves, as it would possibly be true if there were more than three sensations.

If three plates were obtainable, one sensitive to red only, one only to green, and the third to blue-violet, it would obviously be an easy matter to record these three colours, one on each plate. Such plates are non-existent, and in practice the so-called "colour-sensitive" plates are employed in conjunction with colour filters, which trap all the colours not wanted, and allow the others to pass, and impress an image on the sensitive film. These three colours then record themselves as black deposits of silver, and may be printed as positives.

### Additive and Subtractive Processes.

Projecting through suitably coloured light, the three positives will can reproduce "red" by "red light," "green" by "green light," and "blue" by "blue light," and if they are superimposed we shall then reconstitute the colours of the original. Usually the subtractive

method is employed. In this process, the negatives are printed in their complementary colours, which may be tabulated as follows:—

(a) Negative recording "red," as white, minus red, viz., blue-green.  
(b) Negative recording "green," as white, minus green, viz., magenta.

(c) Negative recording "blue," as white, minus blue, viz., yellow. Or carrying the matter a step farther, the three colours will be rendered:—

(a) Magenta + yellow = red.  
(b) Blue-green + yellow = green.  
(c) Magenta + blue-green = blue.

### Printing Inks.

The right selection of colours for printing, Mr. Newton said, was a most important matter, and he showed a series of measurements of various inks, which, as a rule, fell short of theoretical requirements. Blue-green was the worst of all, but the lecturer stated he had obtained a blue-green superior in hue to any of the pigments used in ordinary photographic tri-colour printing processes, but it was not quite satisfactory from the printer's point of view in the way it worked on the machine. The magenta printing inks were also at fault, in not reflecting enough blue-violet, and here the photographic dyes were undoubtedly superior, but printing inks made from these dyes did not usually work well, and generally were fugitive. An original coloured picture was here shown, with flat-etched proofs reproduced with two different blue inks, which conclusively showed the advantage of a blue which reflected more green. The correct inks usually gave flatter reproductions, and consequently incorrect inks are universally used in business. The evening terminated with a display of slides, illustrating points in three-colour and orthochromatic photography, an explanation of the use of selective filters in process work, and a hearty vote of thanks to the lecturer.

### THE RENDERING OF COLOUR CONTRASTS.

The following is a portion of a paper read before the London and Provincial Photographic Association on November 1 by Mr. C. E. Kenneth Mees, B.Sc.:—It is frequently remarked, sometimes as an objection to orthochromatic photography, that since it is not possible to render the effect of colour contrast into monochrome with accuracy, better results may frequently be obtained by avoiding any attempt to correct the true luminosity values.

For example, if we have green and red patches of the same luminosity value in juxtaposition, then, although neither of them will appear brighter than the other, yet they will appear to be very different to the eye. But if they are photographed with a plate and screen which render luminosity values correctly, then they will appear of a uniform tint, and the bright visual contrast will be lost. The usual way of avoiding this difficulty, for it cannot be said to be surmounted, is to use a screen which does not give full correction, and which, for instance, renders the green as lighter than the red.

The chief objection to this course arises from the fact that, if complete correction is not obtained, it is very desirable to know to what extent the correction is incomplete, and it is almost impossible to ascertain this in the manner indicated.

A plan which may or may not be original, but to which I can find no reference, has been designed. If a set of three colour filters be mounted on a slide-past holder fitting in front of the lens, then the plate can be exposed through one, two, or three filters successively so as to make up the total exposure by exposure to different portions of the spectrum. With a "Wratten Panchromatic" plate and "Wratten" tricolour filters, complete correction was obtained by an exposure of  $\frac{2}{3}$  to the green filter and  $\frac{1}{3}$  to the red filter. No exposure to the blue filter is required, as the green records quite enough blue. (It will be noted that orthochromatic rendering will not be obtained by giving the ratio of exposures required for three-colour photography, because this gives isochromatic rendering, in which all colours of equal saturation are rendered as of equal intensity, and not of the intensities which the distribution of luminosity in the spectrum shows them to require.)

Now, having the ratio for correct rendering, we can accentuate any colour at the expense of others to any extent required. Towards the red and  $\frac{1}{3}$  to the green, for instance, gives exalted

reds and degraded greens;  $\frac{1}{2}$  to the red and  $\frac{1}{2}$  to the blue exalted reds and blues and very degraded greens. The whole exposure to the green filter gives much the effect of the ordinary green and yellow sensitive plate fully corrected, but renders reds as blacks.

And in this way error can be introduced in order to facilitate the rendering of colour contrast with the constant knowledge as to the deviation from the truth and the consequent error produced.

### THE NORTHERN PHOTOGRAPHIC EXHIBITION.

In reference to the Northern exhibition to be held in Liverpool in March next, we have received the following announcement from Dr. C. Thurstan Holland, the chairman of the exhibition committee and ex-president of the Liverpool Amateur Photographic Association. Its publication, we hope, will serve to keep before our readers the determination of the Liverpool people to make the second Northern exhibition to be held in their town an advance even on their record of 1904:—

Once more it is the turn of Liverpool to hold the Northern Photographic Exhibition, once more C. F. Inston is the honorary secretary, once more the splendid rooms of the Walker Art Gallery are available, and once more it is hoped to repeat the success of 1904.

It is now ancient history that, as an outcome of the first open photographic exhibition held by the Manchester Amateur Photographic Society in the Athenæum in the spring of 1903, the Manchester, Leeds, and Liverpool Societies joined hands to inaugurate the first Northern Photographic Exhibition at Liverpool in March of 1904. The anxieties of the work of promoting this exhibition are still remembered, but the great artistic and financial success well repaid the organisers.

The illustrated catalogue, based on that of the Manchester open exhibition of the previous year, formed the model for the future shows at Leeds and Manchester. The example of the Liverpool Corporation in granting rooms at the Walker Art Gallery was followed at Leeds in 1905, when the City Art Gallery was used, but not, alas! at Manchester in 1906, as here the corporation authorities did not see their way to lend the art gallery, and the somewhat unsuitable Athenæum was the only other possibility.

From the pictorial photographer's point of view, from the artistic point of view, and from the point of view of the general public, all three exhibitions have been greatly successful, and it is not too much to say that at the present time the "Northern" exhibition attracts the best work of the best workers in the United Kingdom, and can well hold its own with even the two London annuals.

After the splendid collection of pictorial photographs, the standing features have been the series of lantern lectures, the large entry of lantern slides, and the manner of exhibiting these, the catalogues, and the trade exhibits. All the tried successful features of the last three years are to be repeated at Liverpool in the spring of 1907, whilst certain alterations in the line of improvement and advance are to be adopted. Everything points to still another great success, and it is the intention of the executive to leave nothing undone to ensure this success. Manchester is to be congratulated as the originator of the idea of these exhibitions, Liverpool as the organiser to point the road to success, Leeds as the most successful from the pictorial and artistic standpoint, and it now remains to Liverpool to set a still higher standard of excellence for the emulation of her friendly colleagues.

### MR. J. T. SANDELL'S APPEAL.

The following additional contributions to the fund, which we are glad to see is receiving continual support, have been received by Mr. Thos. K. Grant, who with Mr. J. B. B. Wellington will be glad to acknowledge further donations:—

F. B. ....	£2 2 0
Rotherham Photographic Society (per H. C. Hemmingsway) ..	1 2 0
Anonymous (Vienna) ..	1 1 0
Edinburgh Photographic Society (per J. S. McCulloch) ..	2 13 0
Handsworth Photographic Society (per A. E. Teague) ..	0 10 6
Amount already acknowledged ..	122 3 6
Total ..	£129 12 0

## NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.

## ANNUAL REPORT.

THE annual meeting of the National Photographic Record Association was held on Wednesday last at the Midland Hotel, St. Pancras. After some brief informal proceedings, Sir Benjamin Stone (president) took the chair. The hon. secretary, Mr. Geo. Scamell, then presented the following report:—

THE Council of the National Photographic Record Association have the pleasure of presenting their Ninth Annual Report, and it must be gratifying to all interested in the subject to note the steady progress that has been made not only in this country, but also on the Continent, in photographic record work. As a natural consequence of so many local societies now carrying on record work in their own districts, and depositing the prints in local libraries or museums, our own Society has not received as many contributions as in former years, but this we cannot regret so long as records are being made and deposited for public use. At the same time we must again express a hope that photographers will forward us duplicates for the British Museum Collection.

Since our last meeting we have received 372 prints, now making the total of our collection at the British Museum 3,857. From the President, Sir J. Benjamin Stone, we have received 103, comprising a series from Hereford, including views of the Cathedral and the chained library in All Saints' Church, the interesting old Treaty House at Uxbridge where sixteen commissioners for King Charles I. on January 30, 1645, met sixteen for the nation, but the negotiations terminated unsatisfactorily—the house had formerly been the residence of Sir John Bennet, Judge of the Prerogative Court of Canterbury, and afterwards was occupied by Cromwell—some of the old houses and Norman wall at Southampton, St. Cross Hospital at Winchester, and portraits of some of the brethren; Compton, Wynnyates, Warwickshire; door of the old county gaol, Bedford, which was in use when John Bunyan was confined there; from Oxfordshire, Burford Priory House and Churchyard Wall, showing shot marks, and sundry photographs from Gloucestershire, Staffordshire, Worcestershire, and Carphilly Castle, South Wales; a series from Canterbury, including the cathedral and some of the monuments, and the King's School; some interesting records of 1906 pageants held at Warwick and Ripon, including Warwick Castle and Ripon Cathedral, and a specially interesting relic of an old custom, the Old Ducking Stool at Fordwich in Kent.

We are again indebted to Mr. G. Bingley for fifty-five prints, including the Gatehouse and Chapter House of Thornton Abbey, Lincolnshire; font, etc., Burnstall Church, Yorkshire, and from the same county, views of Mount Grace Priory, Charters of Allerton and Kirkstall Abbeys of the 13th century, Byland Abbey and Gatehouse, Rievaulx Abbey and Refectory, and a series of Irish antiquities, Muiredach's Cross, Round Tower of Monasterboice; Cross in St. Kevin's Kitchen, Glendalough, etc.

From Mr. H. W. Fincham—church, monuments, alms houses, and Moor Hall at Harefield, Middlesex; the unique silver processional cross inscribed F. P. DECLVS, 1527, now in the museum at St. John's Gate, Clerkenwell, and a series of St. John, Swingfield, Kent.

From Mr. H. T. Malby, a continuation of his most valuable series of studies of the people of the East End, Sunday morning in Bethnal Green, Limehouse waifs, Bethnal Green children and Poplar gutter children, young hooligans and the mothers of hooligans, Poplar High Street, and similar subjects.

From Mrs. Catherine Weed Ward, a continuation of the series of fonts, including the one in Winchester Cathedral, and examples from the churches of Kent, Devon, Somerset, Derby, Warwickshire, Oxford, Surrey and Yorkshire.

As illustrating some of the sports of to-day we have a series of twenty-one from Mr. Edgar Scamell of the motor trials held in the Isle of Man. May 30, 1905, over a course of 51 miles, when the highest speed recorded was at the rate of 88 miles per hour. The cars photographed include the 90 h.p. car driven by the Hon. Charles Rolls, and those driven by Lee Guinness, C. Bianchi and W. Earp.

Miss J. Niblett has contributed a set having reference to the poet Wordsworth, showing his garden and grave at Grasmere, and views of Bishop Court, Herefordshire, where he stayed in 1827, etc., and the cedar tree he planted during his visit.

From the Hon. Sec., Mr. Geo. Scamell, 124 of the churches of

Essex and Kent, and some of the monuments. From Kent, the churches of Deal, Sandwich, and Minster, and from Essex churches of Fyfield, Little Baddow, Newport, Great Chesterford, Whittle, High Easter, Ingatstone, Barking, Landon, Witham, Dedham, Runwell, etc.

The Association, at the request of the Council of the Photographic Convention, exhibited a series of prints, contributed by Messrs. G. Bingley, E. Scamell and the hon. sec. at their meeting at Southampton, and a set of lantern slides were lent by Sir J. Benjamin Stone and exhibited by Mr. H. Snowden Ward illustrative of record work.

We have received from the executors of the late Mr. R. P. Breton, 1,222 negatives of churches and ecclesiastical details from the districts of North Hants, Rutland, and of the Church Towers of Somerset. As a caution to some amateurs, it may be mentioned that unfortunately some of these negatives, not having been marked or lettered in any way, cannot be identified.

As illustrating what can be accomplished by well-organised and energetic societies, your council would wish to draw attention to the work being done in Essex and Surrey, and it is to be hoped that other counties may be induced to follow their example. The Photographic and Pictorial Survey and Record of Essex had a successful meeting at Colchester on Saturday, June 23, when, after a day's ramble round the old town, the annual meeting was held, which, it is to be hoped, will be the inauguration of a systematic survey of the town as well as an incentive to those able to assist in the work of our general survey and record. The annual meeting of the Photographic Survey and Record of Surrey was held at Kingston-on-Thames, under the Presidency of Viscount Midleton, Lord-Lieutenant of Surrey, who delivered an address, and an exhibition was held in the Art Gallery of the public library of a representative selection from the 2,000 prints already in the Survey collection.

It is also evident that the work is attracting attention in our Colonies, as we have had a letter from Mr. Bladen, Librarian of the Public Library, Sydney, New South Wales, asking for general information respecting record work. In it he states that he proposes to inaugurate in Sydney a similar collection to our own, "as accurate photographic representations of the beginnings of life in Australia will undoubtedly be of great interest years hence."

Reference must also be made to the important meeting held at Marseilles in October, especially as many questions were then discussed of equal interest to the work in this country. The *Congres International de la Documentation Photographique*, under the Presidency of General Sebret, arranged the meeting, to which our President was invited, and various questions in reference to record work were discussed, including such interesting points as to the arrangement in the libraries and method of access, the means of exchange and communication between the various museums and public bodies, indexing and the establishing of a central office as a connecting link for all the existing societies in order to facilitate the exchange of documents, and where a complete list of all record photographs could be kept for reference.

Our own collection has not been of the public value it might have been through not being sufficiently known, and if our funds were in a state to allow of our printing and circulating a complete index of the many very interesting and unique prints now in the British Museum, the collection would doubtless be much more appreciated, and for the same reason your council have been unable to carry out much that they would otherwise have accomplished, and we would now appeal to all interested in record work for a liberal support.

CHRISTMAS P.O.P. postcards are being issued by Mr. H. W. Green, Rotherham. The samples before us bear suitable decorative mottoes on the address side.

THE amateur photographer of Birmingham, according to a report in the "Chemist and Druggist," has another thorn in his side. If the water authorities learn that he uses water to wash his prints he has to pay an extra rate.

At the Society of Arts a paper is to be read after Christmas by Mr. J. Craig Annan on "Engraving and Photogravure." Admission to the lecture, in accordance with the usual custom of the Society of Arts, may be obtained on application to a member or to the Secretary, Sir Henry Trueman Wood, John Street, Adelphi, W.C.

## photo=Mechanical Notes.

### A Patent for Resistant Process Blocks.

According to the Patent Specification of W. F. Cooper, 7, Grosvenor Road, Watford (No. 26,716, 1905) just issued, the process consists in employing for block making a metal plate of greater hardness towards the surface layer, the thickness of the hard layer or layers being such that they are penetrated by the etching at the deeper parts of the finished block, whereby sharper undercut projections are produced.

The invention further consists in employing for block making a metal plate having layers of various hardness decreasing from the surface so as to obtain a stiff and strong form of undercut on etching. A block is obtained having a surface of very hard metal capable of being etched so as to form very strong undercut projections, and with more depth than can be obtained by any method heretofore known to the trade.

In carrying the invention into effect a truly polished surface is taken and coated with plumbago in the well known manner before electro-deposition. We then first deposit a layer of hard metal, such as nickel, then a layer of copper and nickel, the nickel being in predominance, and then another layer of copper and nickel, the copper being in predominance. We then deposit the main body of a plate of copper, the thickness of the nickel layers being such that the deeper parts of the relief penetrate to the pure copper layer.

When a plate manufactured as above described is used for making blocks, the undercuts formed by etching are of a stronger and stiffer character, and the edges of the projections remain thicker and stronger than is the case with blocks heretofore manufactured. The number of impressions that can be obtained from the block is much increased, and at the same time much more perfect impressions are obtained.

Also in order to obtain a fine polished surface for the process block the hard metal should first be deposited to the required depth, and then the softer metal, as if the copper or other soft metal is first deposited, the surface of the block is liable to be rough and uneven.

It will be seen that the blocks having layers of different degrees of hardness may be prepared by other methods than that above described, as, for instance, by rolling, the essential feature of the invention being the use of a plate harder towards its surface than below the surface, the harder material being of such thickness that the etching penetrates the harder material and reaches the softer material.

A CATALOGUE of an exhibition of studies and drawings at the Manchester Municipal School of Art has been produced by the Printing and Photographic Department of the Manchester Municipal School of Technology, now a part of the Victoria University. The volume is a specimen of block-making, printing, and binding of which Mr. Charles W. Gamble, the head of the Department, may be consulted.

## Patent News.

Process patents—applications and specifications—are treated in *Photo Mechanical Notes*.

The following applications for patents were made between October 9 and November 3:—

FILMS.—No. 24,046. Improvements in photographic films. Theodore Birnbaum, 21, City Road, Finsbury Square, London.

BACKGROUND.—No. 24,065. Improved process for preparing combination photographs with any desired background and foreground. Carl Pietzner, 111, Hatton Garden, London.

PLATE-HOLDERS.—No. 24,227. Improvements in photographic plate-holders and casings therefor. Thomas Freshwater Caldwell, 31, Bedford Street, Strand, London, W.C.

SWINGING LENSES.—No. 24,260. Swinging lenses for focal-plane reflex cameras, hand-cameras and the like. Charles Henry Dierks, Aberystwyth, Cardiganshire.

CINEMATOGRAPHS.—No. 24,475. Improvements in apparatus for

obviating the risk of fire in the operation of cinematographs. Hippolyte Martin, 14, Middle Street, Stockton-on-Tees.

CINEMATOGRAPHS.—No. 24,480. Improvements in cinematographs. Ernesto Herrmann, 57, Barton Arcade, Manchester.

LENS-HOLDERS.—No. 24,652. Improvements in lens-holders. Hewlett Scudder and Richard Karl Hohmann, 615 F. St. N.W., Washington, U.S.A.

PHOTOGRAPHS.—No. 24,667. Improvements relating to the production of photographs. Thomas Bolas, 7, Southampton Buildings, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

SELF-TONING PAPER.—No. 5,276, 1906. The invention relates to an improvement in the preliminary treatment of photographic prints made on self-toning paper. The self-toning paper referred to is coated with emulsion, which, in addition to the usual silver and other salts, also contains a certain amount of gold salts. In the treatment of these papers it is usual to employ a preliminary bath; that is to say, the prints are first of all put through a bath composed of a weak solution of sodium chloride or of sulphocyanide of ammonia or other suitable chemicals. The invention consists in the use of solution of aluminium chloride in place of such other chemicals for the preliminary bath.

In carrying the process into effect it is preferred to take the aluminium chloride in the proportion of one-quarter ounce by weight to twelve fluid ounces of boiled or distilled water. The photographic prints, after being washed for ten minutes, are kept moving in this bath for ten minutes or thereabouts, are again washed, and then fixed in ordinary hypo. The photographic prints thus treated are found to possess a very beautiful, rich tone, and the results are highly permanent and superior to those obtainable by the use of the preliminary baths hitherto known.

The two claims are:—

1. Treating prints on self-toning paper in a preliminary bath containing aluminium chloride. 2. A bath for the preliminary treatment of prints on self-toning paper composed of one-quarter ounce weight of aluminium chloride dissolved in twelve fluid ounces of water. Francis John Shepherd, of Park View, Beauchamp Road, East Molesey, Surrey, and John J. Griffin and Sons, Ltd., Kingsway, London.

SQUEEGES.—No. 11,224, 1906. The claim is for a squeegee the upper portion of which is joined to a frame the ends of which are formed in such a manner that the pin by which the rubber portion is connected to the frame has an extended bearing produced

Fig. 1.

Fig. 2.

by the ends of the frame being either coiled, folded, or extended or by other equivalent means.

In an ordinary squeegee, owing to the pressure on the

squeegee when in use, the bearing in the part of the frame through which the pin is passed (being limited to the thickness of the metal of frame), rapidly wears a groove into the pin, and the head of the pin breaks away. In order to remedy this defect an extended bearing is provided for the pin either by bending round the ends of the metal frame and coiling these ends as shown in Figs. 1 and 2, or in other ways. John Wilkinson and Alfred Wilkinson, St. Oswald Street, Rochdale Road, Manchester.

**PLATE-HOLDERS.**—No. 23,226.—The invention consists of a paste-board dark-slide or plate-holder within which the film plate or sheet is offered for sale. This sheath is made of thin, opaque pasteboard or the like, and great economy of space and weight is hereby afforded, the cost of the package being quite trifling, so that after once using the same may be torn to pieces and thrown away without materially increasing the cost of the photographic support.

The improved package may be used not only for flexible, but also for rigid films, plates, and supports of photographic images of any description, the same being ready, immediately after exposure, to be subjected to development independently of any other plate and film which may happen not to have been subjected to exposure. Pietro Torrani, 4, Via Vittor Pisani, Milan, Italy.

## Exhibitions.

### HACKNEY PHOTOGRAPHIC SOCIETY.

FOR three days last week this exhibition was on view in the King's Hall of the Hackney Paths. The hall was brightly lit, lofty and commodious. The trade stalls in the centre were made to look interesting, and the walls, covered with over five hundred pictures, maintained, we need hardly say, the Society's reputation for producing a show that is hard to beat in London, except by the R.P.S. itself and the Linked Ring. In addition to these legitimate attractions, however, the people at Hackney, offered a delirium of delights in the shape of string quartettes, vocal concerts, lantern shows, and finally an award distribution. Small wonder that the annual function wore such an air of life and prosperity.

The awards were positively too numerous to mention. Twenty-five bronze plaques, for instance, savours more of the bun distribution at a Sunday school than of the achievement of awards of merit. Certainly the more the awards the lower the merit. In addition to this wholesale disposal of bronze, there were two silver plaques, three certificates, and an honourable mention. Even the trade stalls came in for prizes.

About half the exhibition was made up of the work of members, and the other was designated as "open." We are inclined to think that the section which showed most healthy individuality was the "Portraiture and Figure Studies" class. In this department were to be seen some novel subjects; and novelty of subject is a rare thing in these days. Mr. Hensler's "Shoeing the Cow" had humour as well as other good qualities. It showed three men concerned in the operation, of which one seemed to be steadying the animal's hind quarters. "A Young Jessop," by Mr. H. W. Lane, was another amusing thing, displaying the antics of a youthful cricketer. One of the best character heads was "The Smacksman," by Mr. H. F. Edmonds. It was vigorous and well treated with regard to the textures of the face, beard, and oil-skins. Many exhibits we had admired before at the two great London shows, and in reference to this fact we must admit to being struck with the curious idea that these particular prints did not look so well on these walls as they did on those of the New Gallery and the Pall Mall Gallery. One reason for this is the unmerciful crowding of pictures at Hackney. Quite one-third of the exhibition might have been dispensed with to the enormous advantage of those that remained. Quantity, it should be remembered, is the easiest thing to get, and counts for nothing; whilst a dozen good things may be seriously discounted by a dozen poorer things hung around them cheek by jowl. Another year we should like to see each picture detached by a few inches from its neighbour. This would entail the covering of the roughly red-ochred boards on which they were hung; and that would be an immense artistic gain. One of the things that seemed to suffer was "The Wayside

Inn," by Mr. Wm. Rawlings. At the Royal Society's show we thought this an exceptionally fine thing. At Hackney we might have passed it as no better than the average, had we not noticed that it had won a plaque. Yet it was possibly the identical print. This reflects upon the general character of the show more than upon the mood of the critic.

Since there were so many plaques to spare we were surprised that Mr. Hensler's "Sunshine and Mist" did not win one. This is work that possesses the qualifications of a good landscape, besides those of an excellent photograph. It represents a little glade copse through which the slanting sunbeams strike with fine pictorial effect. It has all the romance of woodland in it; its tones are true, and its effect convincing. There were many similar effects both in landscape and street scenes, as well as in architecture; but none was better than this. Mr. Roofe had secured the effect nicely in his "Housebreakers," which also had the new idea of men upon wall breaking away with their picks the bricks from beneath the feet. Other styles of work seemed to have a "run" upon them besides this of opaque sunrays. That is probably inevitable in pictorial photography, where the flattering imitation of anything that has been successful always runs strong. More often than not, however, such imitation has the most salutary results. For instance, there were at this show quite a quantity of capitally presented animals of the out-of-the-way type that Mr. Douglas English first brought our notice. There were, besides, the large mammalia of the menagerie, such creatures as prairie wolves, meercats, mongooses, and monkeys. Mr. O. G. Pike likewise has his following, though he, of course, holds the field with his excellent series of such rare birds as kites and eagles, the secret haunt of which he alone knows. The magnificent and all but exterminated birds he shows perched upon their native rocks all unconscious of the nearness of a camera. His "Kite" makes a fine picture by reason of the unusually decorative lines of its body and wings, recalling the best triumphs of the Japanese bird painters.

The point, already mentioned, of the crowding of the frames was naturally most apparent in the architectural sections, because there it was aggravated by the similarity of the subjects. Wherever one looked one saw pillars and arches. When these occur like sardines for arrangement the effect is tiring. Originality seems to run low in this section. Years ago Mr. Evans delighted the camera world with his "Sea of Steps" as he called it, of the Chapter House Wells. He has been frequently copied. There were two more versions at Hackney, and one was "plagued." Mr. Evans, however, had the best right to that bronze distinction.

Not only in animals and architecture do our Hackney friends practice the sincerest form of flattery. One gentleman sent a huge rudder. It was not an iron structure like Mr. Coburn's, but a most picturesque wooden one.

In view of the fact that the exhibition is now closed, it would be folly to speak very exhaustively of individual prints, and even the briefest mention of our favourites would interest nobody but the authors. We are therefore compelled to remain in silence about many works both of members and of that section of the community known as "open," which have given us delight and confirmed our views as to the photographers of Hackney.

### PHOTOGRAPHS BY MR. H. W. BENNETT AND BY MEMBERS OF THE PARIS PHOTO-CLUB AT THE R.P.S.

THE house exhibition at 66, Russell Square takes the form of gathering of prints, for the most part architectural, by Mr. H. W. Bennett. Certainly Mr. Bennett's name is well known, owing to his journalistic writings, his voluminous correspondence upon debatable questions in the photographic Press, and also by his lectures. Yet we should scarcely think that the Royal Photographic Society would hold this, in itself, as a reason for displaying Mr. Bennett's work. On the walls of that stately and rebeautified house usually expect examples that show us a new outlook on photographic art; we look for demonstrations of new processes; for specimens of the skill of workers whose names are new. In none of these respects can we honestly say that the present exhibition is indispensable.

Mr. Bennett makes excellent records of architectural features, details of carving, mouldings, the ravages and stains of time, and so forth. These are perfectly satisfactory as far as they go, but

are they fitted for an exhibition claiming to be artistic and pictorial? These works rely entirely upon their skill and careful technique. Whatever other interests they possess are archaeological, not pictorial.

In a few cases, however, Mr. Bennett has made obvious pictorial effort, as in those he uses the chequered light and shade of ecclesiastical interiors to supply a motive for a picture. This is a field of work wherein mathematical temperament is an incubus. It is not too much to say, perhaps, that the very apparatus which excels in archaeological records is not the very best for good pictorial work, and so altogether Mr. Bennett does not shine as an architectural picture maker. He cannot make an impression. It appears to him impossible to catch a ghost of the overwringing spirit that falls upon and possesses the impressionable being who places foot within a cathedral—that hush, that sense of solemnity and weight and loftiness, the unearthly remoteness of the highest roof and the consequent feeling of the ground as man's inevitable place. He cannot make us realise the atmosphere that the warm, grey walls enclose, or its swelling effect adown the perspectives of nave and choir. In his interiors the distant organ and its little spots of shadow are as clean, sharp, and full-toned as the carved pew stall under our hand. He calls us up no dreams, no holy or hellish associations of history. He gives us guide-book facts and hands us a telescope. Mr. Bennett's knowledge and experience is not doubted for a moment; but he does not press to the front in pictorial matters. His ambition seems to be to beat the photographers of the 'sixties on their own ground.

#### "ARTISTIC LENSES."

By way of contrast, the visitor who steps up to the second floor will see an exhibition of prints obtained by means of anachromatic lenses, by four members of the Photo-Club of Paris, namely, MM. R. Demachy, C. Puyo, G. Besson, and A. Hachette.

These gentlemen belong to that class that is always in a turmoil of excitement for the latest development in ways and means. They are in the forefront, experimenting and delving into technicalities of chemistry and optics, always in the eager hope of finding out something that will bring their beloved art one step higher. And whose work, we may ask, is more instinct with the true artistic feeling?

In our issue of April 13 we went into the question of the new lenses to which these exhibited results are due. What we have now to do is to judge of the artistic merit of their results, and we may say that, taken as a whole, they may be pronounced satisfactory in the extreme. Nevertheless, it is very certain that much of the charm of such works, for example, as Major Puyo's "Etude de Portrait," and "Pronl," is not due so much to the *téléobjectif anachromatique* as to the beauty of the sitter and the unerring taste of the operator. Finer heads, with richer colour and a more delightful soft-sharp definition, we have never seen. It certainly is not always the lens, for the same soft-sharpness in near dark tree branches before a hazy distance which we see in M. Hachette's "Berge de la Seine" is missing in M. Demachy's "Paysage normand," where the strength of tone is accompanied by hard edges. Both of these, however, are by the "Adjustable Landscape Lens." M. Demachy's portraits of Mme D. are perfect pieces of characterisation, and so are his rich and soft portraits of a painter. "Etude du Nu," by M. G. Besson, is a sumptuous piece of lighting, possessing the quality of a mezzotint. Another nude, by M. Demachy, of an entirely different class, is a tiny thing, with lines finely disposed, and of open lighting wherein the modelling is given by the most exquisite gradations of tender tones.

The man counts for much in all these examples, of course, but there is no doubt that the slight remove from hardness and the preservation of firmness that comes of these lenses will make them valuable tools in the hands of artistic workers who are tired of faddy extremes.

### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, the 9th inst. Present: Messrs. G. P. Abrahams (Kewick), F. A. Bridge, Alfred Ellis, S. H. Fry, H. E. Hull, Martin Jacolette, P. Lankester (Tunbridge Wells), A. Mackie, D. Prodder, E. Scamell, H. C. Spink, and Fellows Willson. Mr. Martin Jacolette, president, in the chair.

The collection of photographs by Mr. C. F. Inston recently shown at the Liverpool A.P.A. is now to be seen at the rooms of the Manchester Amateur Photographic Society, 57, Market Street, until December 15. The exhibition is open daily from 6 to 9, on Saturdays from 2 to 5.

Mr. A. Mackie, hon. secretary, said that, in accordance with the resolution of the committee at their last meeting, he had written to the Postmaster-General with reference to the case of the photographic postcard which had been surcharged 1d. on account of the film having become detached at a corner, asking that a deputation of the association be received to explain that photographic postcards were not in contravention of the regulation that nothing may be attached to a postcard except the penny stamp, and had received a reply agreeing to receive the deputation. Since that reply the Post Office had issued new regulations with regard to postcards, and now it was allowable to affix a photograph.

**Artistic Copyright Bill.**—The hon. secretary reported that he had had a long interview with the hon. secretary of the Artistic Copyright Society with regard to the agreement between that society and the P.P.A. as to the provisions to be made for dealing with photography in the new Bill, and it had been agreed between them to suspend negotiations until the Bill in its present condition could be printed, so that the representative of the P.P.A. would be in a position to consider the matter in all its bearings.

**The Annual General Meeting.**—It was pointed out that the date fixed for the conversations of the Photographic Convention was that of the P.P.A. January members' meeting and the experience of this January meeting when the same occurred was that many members preferred the festive gathering. It was therefore agreed that the next January meeting be held on the third, instead of the second Friday, and the hon. secretary promised that, in addition to the general notice in the P.P.A. circular of the change in date, a special notice of the meeting and of all future members' meetings, should be sent to each member.

The hon. secretary referred to a notice published in the P.P.A. circular, of December last, asking members who had had unsatisfactory dealings with a certain background painter to communicate their experience. The attention of the manager of the *BRITISH JOURNAL* had been directed to the methods of the individual referred to, and his advertisements were not accepted. He had succeeded, however, in getting another advertisement inserted from a different address and under an initial, and a member had complained that he had been defrauded. The hon. secretary was instructed how to deal with the matter.

A letter was read from a member suggesting that, with a view to combating the unfair competition of the cheap enlargement canvassers, the association should have a circular printed, warning the public, and that members should be supplied with copies at a nominal price for distribution. The hon. secretary was directed to inform the member that if he supplied the draft the circular should be printed.

#### ROYAL PHOTOGRAPHIC SOCIETY.

**MEETING** held Tuesday, November 13, Mr. J. C. S. Mummery (vice-president) in the chair. Mr. H. W. Bennett delivered a short address on the collection of photographs by himself, which forms the present house exhibition at the Royal Photographic Society. He said that much of the present-day pictorial photography exhibited such deplorable features as imitation of prevailing vogue, imitation of other forms of art, and even imitation of the work of other photographers, in some cases of the work of those acting as judges. The only defensible course, however, was to record one's own impressions in one's own way without regard to any reigning fashion and without the desire of pleasing any judge or critic. Mr. Bennett described his own aims in pictorial photographs as adherence to the qualities which were characteristic of photographs—viz., rendering of form and texture, qualities which, he said, were not obtained in out-of-focus and coarse prints. He regarded the gum bichromate process as retrogressive, as the image produced by it was not that of the lens. Putting a print out of focus, he maintained, destroyed atmosphere and did not suppress detail. Suppression of detail was a matter of lighting, etc., at the time of exposure. A good photograph should possess neither distinct sharpness nor distinct unsharpness at the normal distance. Mr. Bennett believed himself justified in adopting methods of control which could be employed with certainty, but he discountenanced the use

of methods such as gum, by which a number of identical prints could not be obtained. He thought "control" was the wrong word for these processes.

In the subsequent discussion, Mr. E. T. Holding, basing his remarks on a portion of Mr. Bennett's address, protested against the narrow limits within which Mr. Bennett would imprison the pictorial worker. If control was legitimate in one department it was legitimate in all.

Mr. W. Thomas despondently suggested that unlimited control was obtainable by substituting a piece of charcoal and a sheet of white paper for the photographic process. Mr. Thomas was understood to disparage pictorial photography as a means of benefiting the human race.

Mr. Hector McLean demurred to Mr. Bennett's definition of impressionism. Impressionism meant the artist's temperament in his work, and an impressionistic photograph might have any character whatever.

Rev. F. C. Lambert dwelt on the need of knowledge and the evil of imitative methods, and Mr. E. Dockree spoke.

The chairman agreed with Mr. Bennett that it was useless to try and please the judges. He was sorry Mr. Bennett did not favour gum bichromate, as he (the chairman) was sure he would work it very well.

Mr. Bennett, in reply to criticisms, said that his photographs were advanced as expressing his own impressions of the subjects.

Owing to a misapprehension of information received, the report of the opening of the Royal Photographic Society's rooms in our last issue wrongly described Lord Crawford as presiding. This duty was discharged by Mr. J. C. S. Mummery, a fact of which, owing to our inability to be present at the opening of the proceedings, we were ignorant and in regard to which we were incorrectly informed.

**WEST LONDON PHOTOGRAPHIC SOCIETY.**—At the meeting of the West London Photographic Society, held in the Broadway Lecture Hall, Hammersmith, W., on the 9th inst., Mr. W. G. Cullen gave a lecture entitled "How a Dry Plate is Made." After briefly reviewing the process, and illustrating his remarks with test-tube experiments, Mr. Cullen proceeded to make an emulsion. Taking the necessary quantity of potassium bromide dissolved in gelatine, the silver nitrate was added, resulting in the formation of silver bromide in gelatine. It then became necessary to eliminate the potassium nitrate, which is formed with the silver bromide. This is usually done by prolonged washing. However, to expedite matters, it was accomplished by pouring the emulsion into hot alcohol, which must be of the purest kind. The emulsion having become set, portions were handed round for inspection, after which it was coated on glass. Mr. Cullen, not content with this stage only as soon as the plate had set, exposed it behind a negative, which resulted in an excellent transparency.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—At the meeting on Thursday, November 8, 1906, Mr. French in the chair. Mr. W. F. Slater gave a lecture on Holland, and in the course of which he eulogised the country as a hunting-ground for landscape, architectural, and genre photography. He strongly recommended that headquarters be made in such towns as Middleburg, Rotterdam, or Amsterdam, and daily excursions taken into the surrounding country. Plates and cameras gave no trouble with the Customs. Some 150 fine slides were used to illustrate the various places visited, which included Flushing, Middleburg, Veere, Bergen op Zoom, Dordrecht, Rotterdam, etc., each slide being fully described, and such was the pictorial possibilities shown that one wished he could have a three months' holiday and go over at once. An interesting evening was fully enjoyed by the members, and a vote of thanks, proposed by the chairman, was heartily carried.

The Dublin Camera Club has just opened the winter season which promises to be most successful. Papers and demonstration on enlarging, followed up by a lecture on "High-Speed Photography" (this latter by a Mr. Wignall, who hails from Japan), have proved very interesting and instructive. The programme for the remainder of the session embraces, besides, lectures from members on their own photographic experiences, papers and demonstration relating to lantern use, carbon printing, photography in genera

microscopic photography, etc., so that this young club shows evidence of a strong vitality. The secretary is Mr. W. H. Ebbs, of 2, Belvidere Avenue, Dublin. Dublin readers will be interested to know that the club's headquarters are at 1, Upper Sackville Street.

**BIRMINGHAM PHOTOGRAPHIC SOCIETY.**—Mr. A. Pumphrey gave a lecture on the 6th inst. on stereoscopic photography, in which he reviewed this branch of photography as practised by himself and others in past years, saying that in some respects the older methods were the better. He explained the three different methods he had employed in taking the pair of stereoscopic negatives—viz. (1) moving the camera between the two exposures, (2) with a camera fitted with two lenses, and (3) with two cameras separable to any required distance. The advantage of the one-camera method was that pictures could be taken the full size of the original, which, with the two-lens method, would be impossible owing to the distance of the camera being too close for binocular work. A repeating back would enable the two negatives to be obtained on the one plate. When using two cameras the lecturer was accustomed to secure them to a board about 20 in. in length and attached to the tripod top, a slot in the board allowing the instruments to be placed at any desired separation. The lecturer considered it better to mount the negatives than the positives. For this purpose he examined the two negatives in a stereoscope, first finding which was the right and which the left-hand picture. The negatives were then laid down until the most distant objects in each were not more than 2½ in. or 2½ in. apart. The combined negative was best made of the dimensions 5½ in. by 3½ in. (postcard size), and attached to the middle of a half-plate glass plate with gummed strips of paper.

**CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.**—On November 7 Mr. F. Martin-Duncan, F.R.P.S., gave a lecture before the above society on "Forest Life: Studies of the Haunts and Life of some of the Inhabitants." The slides were very much appreciated by those present, and especial interest was shown in some photographs of insect life and micro-photographs.

**WORTHING CAMERA CLUB.**—Mr. A. R. Sergeant, President of the Worthing Camera Club, gave a most interesting lecture on "Ancient Egypt" on the opening night of the winter session. It was illustrated with a number of beautiful limelight views, depicting the temples, tombs, etc. During the course of the lecture Mr. Sergeant remarked that on a future visit to Egypt he should provide himself with many more yards of magnesium wire than he took on the past visit, as photographs of the colossal statues and other beautiful carvings, also the paintings (for which iso plates and screens are essential), in the interior of the tombs, could only be obtained by artificial light.

**PHOTOGRAPHIC CLUB.**—The annual general meeting was held in the club room, Red Cross Hotel, Paternoster Square, on Wednesday, 7th inst., Mr. F. A. Bridge in the chair. The report of the committee and the balance sheet were adopted. The election for the officers and committee for the ensuing year resulted as follows:—Messrs. F. A. Bridge and H. Snowden Ward; committee, Messrs. R. R. Beard, D. Bradford, G. E. Brown, A. Corbett, G. Day, A. Mackie, H. Müller, and C. H. Skillman; hon. secretary and treasurer, T. W. Derrington.

**PLYMOUTH PHOTOGRAPHIC SOCIETY.**—Fleet-Engineer R. A. Shapton, R.N., who opened the lecture session of this society, took as his theme travel and photography as education, though the title of his subject was "In Foreign Lands." He dwelt upon the value of the camera in travel, illustrating his remarks by lantern slides of negatives made by himself in Ohio, U.S.A., Kamtschatka, Korea, Japan, and Venice. In proposing, seconding, and supporting a vote of thanks, those who followed said there could not be the slightest doubt that intelligent observation with the camera could be highly educational. The lecturer had had a bad experience with roll films, but it was pointed out that these were valuable for long journeys, as were cut films, and that, despite shortcomings, the use of them lightened baggage and made for comfort.

At the Northern Tasmanian Exhibition, which opens at Launceston next February, supplementary prizes are offered by Messrs. R. G. Rouse and Rouse (Melbourne). Messrs. Burroughs, Wellcome, and other donors, including the secretary to the exhibition, Mr. Bryant Browne, 112, Brisbane Street, Launceston.

## CATALOGUES AND TRADE NOTICES.

Mr. Robert W. Paul, of 68, High Holborn, London, W.C., sends us his latest catalogue of animated photograph films, a volume of nearly 100 pages, almost everyone of which contains one or more reproductions in half-tone of the subjects catalogued, thus giving the purchaser the opportunity of obtaining a very good idea of the films. The list includes a number of the most up-to-date productions, and we shall be surprised if anyone interested in cinematograph entertainment fails to find it of service. Mr. Paul will send it, post free.

A CIRCULAR from the Metallic Compositions Company, Ltd., 333, Gray's Inn Road, London, W.C., is sent to us, evidently from its inclusion of magnesium powders (guaranteed 99.7 to 99.8 per cent. of purity), of magnesium ribbon, and of photographic flash-powders. The company invites inquiries as to these of its specialties.

## Commercial & Legal Intelligence.

**CANVASSING FRAUDS IN BELFAST.**—In the Belfast County Court last week John Hinds was charged with having obtained sums of 3s. 6d. from Mrs. King and Mrs. Smith, of Little Brunswick Street, by false pretences. Mrs. King said prisoner called at her house, representing that he was travelling for the Irish Art Company, asking had she any photographs she would wish enlarged. She gave him a photograph of her sisters, to be enlarged for 10s. 6d., payable by instalments. She paid him 1s. then, and weekly instalments up to 3s. 6d. She called for the photograph, but he said the enlargement was not finished. She never got the photograph or enlargement. The constable who arrested the prisoner stated he found four photographs in his possession, and at his lodgings forty-one photographs, and a number of billheads purporting to be issued by the Irish Art Company, State Chambers, 75, High Street. There was no such company at that address. About twenty people had come to him (the constable) claiming photographs given to the accused. Prisoner was remanded for a week, Mr. Taghan, who defended, protesting that the proceedings were uncalled for and monstrous. Prisoner had an agency for a well-known London firm, and the photographs in question would have been enlarged in due course. Bail was fixed at £10.

**HARD LABOUR for a Canvasser.**—George Seals, described as a canvasser, of Nottingham, was charged at the Shire Hall, Nottingham, last week, with having obtained 3s. from Mrs. Hatfield, a similar sum from Mrs. Dring, and 2s. 6d. from Mehalah Braybrook, all of Carlton, during October. The alleged fraud consisted of the collection of instalments on photographic orders that he had obtained as a canvasser for a Nottingham photographer, but the defendant denied having collected the money with any fraudulent intent, but as a convenience for the customers. The Chairman remarked that Seals had a bad record, as he had twice served terms of imprisonment amongst other things, and he would have to go to gaol for two months with hard labour.

**A SMALL FAILURE.**—In Dundee Sheriff Court, on November 8, before Sheriff Campbell Smith, a petition for cessio was brought against Messrs. Elder Bros., art photographers, Broughty Ferry, by Messrs. John Dawson and Son, wholesale stationers, Kirkcaldy. The bankrupts began business in July, 1904, and did not feel themselves pressed until the spring of this year. They attributed their failure to dull trade during the winter. The assets amounted to £53, preferable claims totalled £31 3s. 1d., while the liabilities were stated at £205 1s. 3d., giving a dividend of 2s. 1d. per £1, subject to expenses. Sheriff Campbell Smith granted the petition, and appointed Mr. W. L. Clark trustee.

**PHOTOGRAPHS in the "Bondman."**—Mr. Justice Neville, in the Chancery Division last week, gave leave to the Dover Street Studios and Art, Ltd., to serve notice of motion for to-morrow week for an injunction against Mr. Hall Caine, the Associated Newspapers, Ltd., and Ballantyne and Co., Ltd. Counsel for the plaintiffs stated that his clients were the registered proprietors of certain photo-

graphs which had been reproduced and put in a book called "The Bondman."

**A LIKENESS Case.**—An enlarged photograph was the subject of proceedings at Limerick Petty Sessions last week by Miss Margaret Carey, who summoned the "L. and I. Portrait Company" to recover 14s. which she had paid by instalments for the enlargement of her photo. "The picture," she said, "but for the blouse, might be anyone" (laughter). "I think," said Mr. Hickson, R.M., "the picture is very like the photograph. Look at the lock of hair." "My eyes and hair are all wrong," replied Miss Carey (laughter). "These are the colours she gave us," said the defendant, and the Bench ruled a dismissal.

## News and Notes.

**THE Convention Social.**—This enjoyable function, which was so successful on the last occasion, has been fixed for Friday, January 11, at the galleries of the Royal Society of British Artists, Suffolk Street, Pall Mall, London.

**ROYAL Institution.**—A Christmas course of lectures, adapted to a juvenile auditory, will be delivered at the Royal Institution by Mr. W. Duddell, on "Signalling to a Distance; from Primitive Man to Radio-telegraphy." (Experimentally illustrated.) The dates of the lectures are December 27, 29, 1906, January 1, 3, 5, and 8, 1907, at three o'clock.

**CINEMATOGRAFH Accident.**—A piece of hot carbon dropped into a basket of biograph films in a theatre in Evansville (Indiana). The films instantly flamed up, causing a wild panic.

**LONDON and Provincial Photographic Association.**—On Thursday, November 22, visitors will be heartily welcomed at the White Swan, Tudor Street, E.C., when Mr. A. J. Bull will lecture upon "Bathed Plates and Ortho' Work up to Date."

**PINATYPE Demonstrations.**—Messrs. Fuerst advise us that they are arranging to give a limited number of demonstrations of the "Pinatype" process of colour photography before photographic societies in and around London, and will be pleased to hear from any secretaries who may desire their demonstrator to visit their society, with particulars as to open dates.

**THE Ilford Urban Council** has refused permission for its seal to be photographed for reproduction on picture postcards.

**THE funeral** of the late Mr. William Hill (of the firm of Messrs. Hill and Son, photographers, Standishgate) took place last week at the Wigan cemetery.

**THE Cinematograph on Steamships.**—A fresh method of entertaining passengers on a long voyage is to be tried by an Italian steamship company. British shipowners have been approached time after time to install bioscope, but they have turned a deaf ear to every project, and it has been left to a foreign company to initiate a new movement and to popularise its route by nightly entertainments with the aid of the cinematograph.

**A BRONZE medal** was awarded to the Beck Celverex shutter at the Hackney Exhibition. Messrs. Beck's stall was of a novel and attractive character, a clock tower which surmounted the edifice serving to give prominence to the new shutter. A bronze medal was also conferred upon Messrs. Burroughs, Wellcome, and Co., for their exhibit of "Tabloid" photographic chemical.

**A SILVER salver** has been presented to Mr. Lang Sims, the treasurer of the P.P.A., "in recognition of his valuable services as secretary of the Conservative Party on the Lambeth Borough Council."

**STOLEN Lenses.**—The following lenses have been stolen from a messenger going to the premises of Mr. C. P. Goerz, of 1-6, Holborn Circus, E.C., and a reward for their return is offered by the firm from whom they were stolen:—1 Goerz Telephoto Attachment, IIB, 48, m/m 156765; 1 Goerz Double Anastigmat IB/o, 111273; 1 Goerz Pantar Combination, No. 11, 14in., 183825, 11½in. 183497. Any gentleman coming across or being offered any of these lenses will oblige by immediately communicating with Mr. C. P. Goerz.

## Correspondence.

*\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.*

### ARC LIGHT IN THE STUDIO.

To the Editors.

Gentlemen,—In your issue of October 26 I notice you were good enough to refer to the demonstration held here before the Light Committee of Middlesbro'.

As some particulars may be of interest to your numerous subscribers I should be very pleased to place them at your disposal.

The light I have installed here is, in some respects, different from that constructed from what is generally used, and its cheapness and portability would give it many advantages.

I use four open arc lamps in series, suspended on an iron frame work, running on large metal castors, constructed so as to be taken readily asunder. Each light has a suitable reflector behind it, arc, arranged at an angle so as to project the rays downward upon the sitter. In the front of the light there is a transmitting screen of thin gauze, which softens and diffuses the direct rays.

This arrangement has many advantages. The light generated is from a lamp, horizontally placed in a reflector, which causes considerable loss of light, from the fact of the light being reflected.

My light is perfectly noiseless, as the lamps are perpendicular and automatic, and a considerably greater power of light is obtained by the use of the arc in this way. The cost of a similar installation covering all expenses ought not to exceed £15.

Should any further information be of interest I shall be pleased to place it at your disposal. Regarding the merits of the light, I shall leave this to your judgment. I forward a few prints of the first photographs taken with it.—Yours truly,

R. E. FAIRCLOUGH.

93, Linthorpe Road, Middlesbro'.

November 12, 1906.

[The four photographs (retouched) sent by our correspondent are very harmonious prints, evidently from fully exposed negatives. It would be interesting if our correspondent gave the actual figures of plate, stop, and exposures.—Eds. B.J.P.]

### DEVELOPMENT WITHOUT ROCKING.

To the Editors.

Gentlemen,—Reading in the current number the article by Dr. Neuhaus and your remarks, I am led to mention some facts bearing on the principle there laid down. Some dozen years ago, passing a period of three years in Switzerland, near Lausanne, before going again to Germany, I had got out my photographic apparatus again, and was making trials of new plates and papers which I found on the market, as well as of different photographic processes. Among others, while in England during the Christmas holidays, I had procured a certain number of the Christmas illustrated periodicals, that I might gain experience in photographing engravings. I had also gone to Messrs. Marion and arranged with them to prepare a dozen of their medium plate 12 x 7½ for a Geo. Hare camera specially made for me, and to send them with others which at that time were supplied to an agent in Lausanne. While waiting for these I had fixed uprights at the end of a broad board—my drawing board—to which to fasten the engravings with drawing pins, and placed my camera on the board, so that I could fix it at different distances, and focus the print to the right size. In this way, bringing it up to a window open to the sky, I could most easily expose and learn for such kind of plate the time necessary for the larger plates came. I obtained from the agent here a half-plate packet of Marion, with the same vignette. Believing them to

low plates, such as I had ordered, I exposed accordingly, and found the plate on developing, altogether beyond control, and in my further exposures treated them rightly as rapid plates. When the 12 x 7 1/2 in. plates came, I believed they would be the same, and exposed the first of them accordingly, on a fine engraving of St. Paul's Schools, London. When I came to develop, it seemed like a plate that had not been exposed, and if I had forced it I should have had a hard, worthless negative; but I had formerly read many things in the Journal, in different numbers of the ALMANAC, and elsewhere, and recollecting the theory of the weak developer, I diluted it, covered up the developing dish, and when I came back, after several hours, found the negative beautifully developed, entirely harmonious and satisfactory. The theory given in what I had read on the subject was a little different to that mentioned in the article, but in substance amounts, I think, to the same thing. It was said that the developing fluid, standing immediately over the more fully exposed parts gradually exhausted its developing power in these, while that over the less exposed parts continued its work reducing the under-exposed parts. The glycin, I suppose, renders the fluid less mobile and so favours this action.—I am, dear Sirs, faithfully yours,  
W. WASHAM.

Villa Cornelia, Chemin de Villard, Lausanne.  
November 12, 1906.

To the Editors.

Gentlemen,—The article in last week's Journal reminds me that have practised this method for some years, and with the glycin developer recommended by Herr Walter. Nothing can be more satisfactory. I dilute the usual stock developer ten times, and development is complete in from a quarter to half an hour, according to circumstances. There is absolutely no mottling, as with the usual developer when worked still. Now it is well known that the usual developer shrinks the film and renders it less penetrable; on the other hand, the strongly alkaline glycin developer penetrates with ease. It would appear therefore that any developer, generally similar to glycin and similarly used, should work more or less advantageously, and this, whether the dish be rigorously level or not. At any rate, I have never taken any special precautions to keep the plate properly horizontal. Still, development with the glycin developer enables one to arrest development more exactly to one's wish than is the case with the usual method.

EDMUND J. MILLS.

64, Twyford Avenue, West Acton, W.  
November 10, 1906.

#### PHOTOGRAPHIC SOCIETIES AND THE PRESERVATION OF HISTORIC BUILDINGS.

To the Editors.

Gentlemen,—May I draw your attention to the marked paragraph in Selby Abbey, on enclosed circular, and suggest that other photographic societies might be invited to do likewise.

Photographers are greatly indebted to the authorities of the various cathedrals, abbeys, and churches throughout the country for the privileges afforded to them in connection with the photographing of these buildings.

Many members of societies would, no doubt, be willing to contribute a small amount to a society fund, which they might consider as trifling to send direct.—Yours faithfully,

JAMES W. WRIGHT,  
Honorary Secretary.

Sheffield Photographic Society.

The paragraph runs as follows:—

"Selby Abbey Fire.—The council have decided to open a subscription list, in the name of the society, towards the restoration fund. Subscriptions of any amount may be forwarded to the honorary secretary."

[We commend the public spirit of the Sheffield Society, and hope to see the concrete expression of it in a list of donations.—EDS. J.P.]

## Answers to Correspondents.

\* \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\* \* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

\* \* \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

- F. Foot, 6, Pitt Street, Jersey. Photograph entitled, "Ye Olde Jersey Milk Can."  
D. Ross, Norman Place, Leslie, Fife. Photograph of Inchdairnie House Leslie, Fife.  
A. Walker, 86, Queen Street, Maidenhead, Berks. Photograph of the Interior of High Wycombe Town Hall.  
W. Elliott, 98, Bordesley Green Road, Birmingham. Photograph of an Oil Painting by W. Eddy, Representing a Nymph Reclining.  
H. Shrivington, 10, Church Road, Cadroxton, Barry. Photograph of Whitmore Bay, Barry Island.  
C. C. Bedford, Carr Street, Ipswich. Photograph of the New Hall and Offices, East Suffolk County Buildings, St. Helen's Street, Ipswich.  
W. Baldry, 69, Fores Road, Nottingham. Photograph of a Drawing of Nottingham Forest about Sixty Years Ago.

BOOK ON ARTIFICIAL LIGHT.—I want to take portraits at night by artificial light, and would be very much obliged if you could give me any information about it. Is there any book published on the subject? If so, where could I get one? I have looked through the list of books in your ALMANAC, but I do not see any there.—A. H. STYLES.

There is no book other than "Magnesium Light Photography," by F. J. Mortimer, published by Dawbarn and Ward at 1s.

W. WASHAM (Lausanne).—We can only suggest that you now apply to Messrs. Guitermann, 35 and 36, Aldermanbury, E.C. They are wholesale dealers in celluloid, but they might, as a matter of courtesy, supply you with the precise weight of the material which you require.

FORMULÆ.—Can you give me a good formulæ for (1) reducing hard negatives so as to bring to proper printing density without making the shadows too thin—that is to say, which will affect the high lights more strongly? (2) Ditto for intensifying hard, thin negatives, to intensify the whole image, and not only the high lights, as mercury does? (3) Can amidol be used in re-developing after reduction by Eder's method?—G. E.

(1) Ammonium persulphate, 10 to 20 grs. per oz. (2) The uranium intensifier, or Wellington's silver intensifier. (3) Yes.

ENQUIRER.—See the paragraph on "Stage Photography," on page 899, of last week's issue.

VIATOR.—The article on September 9, 1904, was by F. Grenfell Baker.

FLASHLIGHT.—Will you please give me your advice as regards the following, and oblige? (1) What lens should I use to take a flashlight dinner party, in a room about 20ft. long, people to be sitting at table? (2) Would three or four flash candles, to burn two or three seconds, be better than a flash of powder?—P. A.

(1) If you can get sufficiently far back to include all the party, an R.R. lens will be about the best to employ. If not, you will have to use a wide angle lens, which will be slower in action. (2) Either will do, but by using the flash, there would be less chance of movement of the figures than there would be with a light burning for some seconds.

FLASHAXE.—A good deal depends on the surroundings, i.e., on the amount of reflected light, but we should think the light you suggest would suffice. But the best advice we can offer you is

that you make a trial exposure under as nearly the same conditions as you can.

**RETOUCHING LANDSCAPE PHOTOGRAPHS.**—Could you kindly, through the "Journal," indicate to me any little work giving concise instructions for the retouching of landscape photographs? I have an excellent one in German for portraits and groups, but my work is almost entirely with landscapes.—W. W.

We know only "Retouching," by Arthur Whiting (Dawbarn and Ward, Ltd., ls.), which deals with the treatment of landscape negatives.

**J. HARRIS and Others.**—In our next.

**ALUMINIUM SHUTTERS.**—I have a half-plate hand camera, the shutters in the dark slide of same being made of aluminium, and I find that if I leave plates in these slides a day or two they are invariably fogged. Can you tell me a way I can black the shutters, or otherwise avoid this fog?—CORNISHMAN.

This subject has been dealt with recently in several of the German papers, and the conclusion come to is that if the aluminium is varnished there is no action. The formula for blackening aluminium will be found on p. 989 of the ALMANAC for 1906; but we should think it would be preferable to give them two or three coats of a hard varnish, such as celluloid, if it is considered desirable to use a black varnish, then some asphalt and lampblack, or the latter alone, might be added to the varnish.

**TONING BROMIDES, ETC.**—(1) Will you kindly tell me what varnish is used for coating toned bromides to prevent fading? (2) I shall be glad if you can give me any information regarding the permanency of toned bromide and gaslight prints, using the following processes (Dr. E. Sedlaczek's): "The Iron Process," page 625, B.J.P., 1906; "The Copper Process," page 645, B.J.P., 1906; "The Ferricyanide Process," page 646, B.J.P., 1906. (3) I am extremely obliged for the answers to my former queries, and should like to mention, with reference to the ammonium persulphate query, that I used a 2 per cent. solution of the salt, at least three days old, on well-washed plates and films. Reduction proceeded normally on former, but hardly at all on latter.—GEORF.

(1) An ordinary celluloid varnish is probably the most satisfactory, as this does not confer any gloss on the prints. The usual strength is 5 grains of celluloid in an ounce of amyl acetate. (2) Whilst the tones obtained by all these processes cannot be considered as absolutely permanent, there is no doubt that, with proper treatment, the prints will stand for a long time. The copper tones are more stable than those of iron, but the latter can be improved by treating the prints after toning to a 2 per cent. solution of hypo. Probably the ferrocyanide process on p. 646 would give the most permanent results. We may add the caution that when Dr. Sedlaczek advises the use of hydrochloric acid great care must be used not to exceed the quantity stated, otherwise trouble is sure to be met with, and with some of the formulæ if the acid be increased the tones stated cannot be obtained. (3) We have never met with a case in which persulphate would not reduce a film, and can only imagine that some hardening agent was used as a developer, or subsequently. It would probably be worth while trying sanzol on the films.

**FOREIGN INFRINGEMENT.**—A number of my photographs, taken in a Portuguese colony, are being copied, and reprints done from them at a cheap rate in Italy. Can you tell me, through your paper, whether I can do anything to stop this, as there is no protecting copyright law in Portugal? Can I stop it in Italy, and if so, how?—ANGLO.

The infringement being in Italy, and that country subscribing to the Berne Convention, you have the right to take action. It is a clear case of infringement. We advise you to put the matter in a solicitor's hands. The law of foreign copyright is dealt with to some extent in the 1906 ALMANAC, p. 680.

**L. E.**—(1) You give us absolutely no idea of the method of working, so that we can only make a guess in the dark. The small black specks are due, we think, to metallic or chemical particles which have settled on the print prior to toning; these can be prevented by immersing the print before washing in a 10 per cent. solution of salt. The dark brown stains on the boys' portraits are

due to dirty fingers, as the corrugations of the skin are clear to be seen. Some of the round spots with light centres are due to splashes of something, or metal particles coming in contact with the print after fixation. The chief fault with your "autumn" picture is, of course, the obvious posing of the figures, and the distorted perspective for the men at the back are pigmies, compared to the boy, and the front horse is mammoth compared to the plough horse. The distance is rather too heavy and distinct, due, we should imagine, to too small stop. We are afraid it would stand little chance in an exhibition.

**ART EMPORIUM (Vancouver, B.C.).**—The view publishing business here has been practically supplanted by the postcard trade, and the most useful outlets for your photographs are the large postcard publishers, such as Raphael Tuck and Co., Raphael Houmoult, E.C.; or the Photochrom Company, Hosier Lane, E.C. "The Picture Postcard," published by the Postcard Publishing Company, Imperial Buildings, Ludgate Hill, E.C., is the only journal, and will give you an insight into the trade.

**FREE-PORTRAIT FRAUDS.**—Tanqueray's circulars have appeared in this district, and I have been asked by many if his offer is genuine. Unfortunately, many have already sent him money. To prevent others doing likewise I should like to have some copies of the "Judy" skit on free-portrait swindles which appeared in the B.J.P. of September 7. I shall be very thankful if you will kindly let me know where I can get those reprints to buy, and the price.—W.S.

The reprints were issued by the Professional Photographers' Association, 89, Albany Street, London, N.W. If you are a member you can obtain them from the Secretary, to whom you had better apply for further information.

**TERMINATION OF SERVICES.**—I am engaged by a photographer as a weekly employee, having to work seven days a week. When taking the situation I was promised work for the winter, and consequently gave up an idea of going abroad. On Saturday evening I received a week's notice, saying that the place was being closed. My question is this: I started on a Saturday morning, which would mean my week ending on Friday night. Am I bound to accept this notice, as, in my opinion, I should have received it on Friday? I found it was posted at 12.15 p.m. in London on Saturday, and I received it at 4.15 the same day. I should be greatly obliged for information in reference to this.—H. GREGORY.

It is usually understood that the working week begins Monday morning and terminates on Saturday night, and, presume you were paid on Saturdays. Therefore you receive a full week's notice, which is all that is required. It seems to us that you should have been paid for the day's work on the Friday Saturday you were there. A mere verbal promise that you should have work through the winter is of no value. An agreement to that effect should have been made in writing. It is a pity that assistants, when making engagements, with promise of winter employment, do not have a written engagement to that effect, with a sixpenny stamp affixed. Verbal promises are of no value.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Photographic Record and Survey. We publish a paper by Mr. James Harrison read before the British Association in which the value of photo-survey work is insisted upon and the organisation detailed. The Marseilles Conference of Photographic Record has taken place, and, as reported in our last issue, the spread of survey work in other countries was mentioned by Sir Benjamin Peacock at the meeting of the National Photographic Record Association last week. We draw attention to the desirability of a central directing body to undertake the work of classification of the records. (P. 923.)

Free-portrait canvassers who have been busy recently in Perth and Rosmoy, Hants, have had a warm time owing to the exposure of their methods in the Press and the personal opposition of the photographers. We give a lengthy report proving over and over again the fraudulent nature of the business. (P. 932.)

The Traill-Taylor Lecture. We give the text of Mr. E. Walter Maunder's very interesting lecture delivered at the New Gallery on November 23 on "Photography in the Work of Greenwich Observatory." (P. 926.)

Frequent applicants for advice on so-called "Rembrandt" lighting are advised to refer to the article on Page 930.

The precautions which should be observed in taking out a policy of fire insurance are the subject of an editorial on Page 922.

A country professional reader records his satisfaction with the Christmas trade brought in on his adopting a suggestion in the British Journal. (P. 938.)

A case in which a pugilist claimed damages for libel by cinematograph films has been dismissed. (P. 938.)

Technical classes at photographic exhibitions. The Southsea Society deserves commendation for its endeavour to foster the technical side of photography. (P. 933.)

J. Antoine Lumière, of Lyons, has been made an officer of the Legion of Honour, in acknowledgment of his firm's contributions to colour photography. (P. 937.)

## EX CATHEDRA.

### Technical Classes at Exhibitions.

For some years now the wave of pictorial photography has been sweeping over the country, and has, certainly at provincial exhibitions, entirely swamped the technical side. It is, therefore, with a good deal of pleasure that we note that an attempt was made by the Southsea Photographic Society, at their exhibition held this week, to encourage technical and scientific work by a special class both for prints and lantern slides. Whilst the response was hardly so satisfactory as regards numbers as one would wish, we think that the committee of the above society should be thoroughly satisfied, not only for having had the courage to recognise this side of photography, but also because they have set a good example to others. Looking at it from a sordid point of view, a technical and scientific class means the pocketing of entry fees which would not otherwise be obtained. From the point of view of the outside visitor, the visitor who does not use a camera, one can well understand that such technical exhibits as bird and animal studies may appeal far more than the finest nocturne buried in the gloom of gum, for the simple reason that the latter is utterly beyond his powers of understanding.

\* \* \*

### Is Good Technical Work Easy?

The plea, sometimes advanced, that good technical work is easy will not hold water. It may be possible, under the present conditions, when everything is made for him, for the mere beginner to turn out a print showing good technique as regards mere printing and mounting, but it is entirely a different thing when it comes to the specialisation of photography in certain directions, whether it be bird, animal, or fish life, or even what is always considered a very easy subject, the proper rendering of flowers and fruit. The photographer who uses his tools merely for the production of good technical work, or even for mere records of places he visits, without any hope of attaining to the pictorial heights of the leading workers, has a vast field open to him, in which his technical skill will not only lead to satisfaction to himself, but give immense pleasure to those who like to see something which they can understand without a long explanatory title, even though this be three or four lines of poetry. It is not necessary to follow the bird photographer into swamps or down almost inaccessible cliffs, but there are around us innumerable subjects that can be made, if specialised, interesting, and almost every one of these special branches calls for skill of an order above that of the average commercial photographer.

### The Pyro-soda Developer.

We have received from a correspondent three negatives, developed with the three formulæ, A, B, and C, which we gave on page 863. All these negatives were exposed for the same time, and developed for the same time, and the three are very much alike, with the exception that the one developed with formula B shows that the bromide has had a slight effect. This experiment is valuable, but we are afraid our correspondent has mistaken the points at issue. There is no reason known to us for expecting that these developers corresponding to our table would show any marked differences if made up in the same way. The differences occur when the mixing of the solutions is varied. In the formulæ represented by A and C the metabisulphite and sulphite are both kept in the pyro stock solution, the carbonate being dissolved alone in a second bottle. In B the metabisulphite is with the pyro, and the whole of the sulphite is contained in the same bottle as the carbonate. These are the essential differences. The result is that while A and B keep better than B and give quite stainless negatives, even when months old, yet they are both very much slower. In the table, both are diluted, B being full strength. To make A work with something like the same rapidity as B the solution must be concentrated until it contains at least 4 grains of pyro to the ounce. Mr. Herbert, in his formula, uses 4.4 grains. Our correspondent does not state the temperature of the developers, but simply explains that he developed for nine minutes. His negatives differ so little that it is evident the method of mixing has either increased the speed of A and C or reduced that of B. Possibly both effects were produced, for the negatives are all of fair density, and if the temperature was anything like normal nine minutes is rather a long time for B, and much too short a time for our formula when diluted down to the strength of A. The experiment is very interesting, and appears to offer a possible clue to the varied behaviour of the stock solutions used in our formula and in Mr. Bennett's. If our correspondent can supplement his information by giving the temperature at which he developed, and will also state the precise manner in which he mixed formulæ A and B, we shall be greatly obliged. The details of mixing cannot be too precise, for much may depend on the manner and order in which the ingredients were dissolved.

### The N.E.A.C. and the R.W.S.

The New English Art Club is not lying up to its reputation. Its mad, irreverent, revolutionary spirits are on the wane, and the show begins to be disappointingly good and sane and earnest. The brilliant and masterly landscapes of

Prof. Brown are no longer "New English," but admirable old English, and so are the excellent London street scenes of Mr. F. Dodd, and the strong and early-mannered sketches of Mr. Rich, to mention these only. The romanticism of Mr. McEvoy and the earnestness of Mr. C. J. Holman quite outshine the vagaries of one or two artists who may yet have shown a piece of work taken beyond the career sketch stage—perhaps for a good reason. We think that the best exhibition yet of this society. The Royal Water Colour Society, on the other hand, is content to be known as "old," not as "new," and its exhibits are always freshest, because the cleverest and best of them all, mention names would be futile. We recommend all to desire an artistic treat, to know what is meant by pictorial qualities, and to see what lies within the range of the artistic temperament in the employment of colour and values, the charms of style, composition, and all else makes a perfect picture, to spend a shilling at No. 5A, Mall, now, not when the walls are lined with drab and the gallery sports a Frenchified name.

### FIRE INSURANCE CLAIMS

A QUESTION of some importance to photographers generally is put to us by a correspondent this week with regard to compensation for injury to negatives arising from a fire on the premises. In his letter he says that some thousand negatives have been quite spoiled, presumably by water, as the other damage was not great. He adds that the insurance company seems to regard them as of no value whatever, as they were not in use and were only valuable in the case of re-orders. If the negatives are named in the policy as part of the property insured, he certainly can claim for their value. But the question arises—what is the value of an old negative? The insurance company's contention in this case is that it is only valuable in the event of copies being required, and that is a reasonable one. In most policies the value of any individual negative is limited to a certain small sum—such as sixpence or a shilling. But it must not be assumed from that that the amount can be recovered for all those destroyed. The insurance company will require proof that those that were had value to the insurer, which is a somewhat difficult matter. Now the question arises: What is the value of a stock of old negatives? We think that it will be admitted that as a rule, by far the larger proportion of them are valueless.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1907.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-sixth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached the total of 1,616 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1907 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

### THREE-COLOUR PHOTOGRAPHIC PRINTING PROCESSES,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1907 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1907 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—Our publishers ask us to inform Agents that it will be as well to place their orders for copies immediately, as the issue is always booked before publication, and a second edition will not be printed.

there is but little probability of copies ever being required from them; they are simply useless lumber and not worth the room they take up. The case may be different with the negatives of public characters, but we are referring now to a general portraitist's business. At the present time the re-orders from old negatives are very different from what they were a few decades ago. Then people did not sit so frequently for their portraits as they do now. The orders for copies from old negatives were more frequent, even if they were years old—sometimes because the portraits appeared more youthful than if they were freshly taken. With present-day retouching methods at condition does not still obtain. In the case of each it is the last portrait that was taken which is the one usually required. As portraits are done so cheaply now, and fashions, especially amongst ladies, change so frequently, it is usual for people to prefer to sit again rather than order from previous negatives, in which they are portrayed in out-of-date costumes. Hence it will be seen that a stock of portrait negatives is not of the same value it used to be at one time. One frequently sees, when a business is advertised for sale, so many thousands of negatives mentioned as being a valuable asset, but are they so valuable after all? The only way to assess the true value of a stock of old negatives, whether in the case of fire damage in the sale of a business, is to ascertain the amount they bring annually in the form of re-orders.

Photographers, when they effect an insurance on their property, are frequently very negligent in the matter. In many cases the insurance is effected through a local agent, who takes down rough particulars and receives the first premium: the policy is forwarded from the head office. Of course this arrives, and the insured simply reads out the amounts of the different things are rightly specified and then rests content. He very frequently fails to read the terms or more conditions upon which the policy is issued, and the infringement of any one of which is sufficient to invalidate it, and no claim in the case of fire can then be legally sustained. Furthermore, when a policy is once invalidated it is always void, even if premiums upon it have subsequently been paid. In most policies there is a limited sum placed on different items insured, as in the case of negatives, or, for example, lenses, that no one exceeds a value of, perhaps, £10. Thus, if one is worth £50 no more than ten can be recovered if it happens to be destroyed. The same with pictures and the like. If lenses or other items of high value are to be insured, the insured must see that the fixed limit includes their value. One of the conditions of a policy is that the company reserves itself the right to reinstate what has been destroyed. This does not mean that it will supply new goods, but only that as those destroyed. This is very rarely done, yet the office cannot be expected to pay the price of new things for what are secondhand ones. Although all policies contain such a number of conditions that they may easily, unwittingly, be rendered void, companies usually deal fairly, sometimes very generously, with their customers, when they are satisfied that when a claim is made on them it is a reasonable one, and that it is not made with a fraudulent intent.

the collections now being formed in various provincial centres. Photographers who thus employed their leisure have now the satisfaction of seeing their labours emulated in other countries. In France the movement is being promoted by an eminent committee; the United States, as a result of Sir Benjamin Stone's exhibit at St. Louis, is taking steps to organise a national effort; Australia is asking for guidance; and Japan has proclaimed its intention of recording its national scenes and customs by photography. Record photographers, therefore, may feel a pardonable pride in these evidences of approbation, the only ones almost to fall to their lot. Unlike the practitioners of "pictorial photography," the photographers devoted to record work can hope to make no bubble reputation, nor be flattered by reproductions, usually unlike the originals, of their works in the amateur papers. Such signs, therefore, of the importance attached to their unadvertised labours should be all the more gratifying, and at the same time stimulate individuals and societies who have hitherto taken no part in this greatest and important application of photography.

But to drop a complacent tone, we would point out the danger which exists of the energies of present and future participants in photographic record work being wasted, and we would lay stress on the urgent need for central organisation and direction. This need, we think, is just as real in regard to the classification of record completed photographs as in regard to the supervision of work undertaken. In fact, in view of the final aim of all record associations, that is to say, a complete pictorial history of the present time and of the relics of previous historical periods, it is more important to have a complete and workable scheme of classification than it is to avoid the same work being done twice. The former impairs the usefulness of the work at any stage towards completion, whilst the latter merely gives the opportunity of discarding a number of photographs for better ones. The time would seem to have come when a committee composed of representatives of the record associations and of one or two persons accustomed to classification, such as librarians or indexers, should prepare a series of sections and sub-sections for the classification of the photographs already made, and, more important still, of the immensely larger amount which will be added to the number. From our experience of filing documents it seems to us inevitable that every print in a record collection must be a separate unit, removable from its present place and transferable to a different series. The mounting of prints in albums, unless the leaves are removable, is a course which we cannot discountenance in sufficiently strong terms. Every provision should be made for the growth of collections and any re-arrangement which future work may show to be desirable. The wisdom of this course, we believe, will be obvious to anyone who has had experience in filing information, correspondence, or any documents to be referred to at a minimum of trouble.

The question of cataloguing is one which Sir Benjamin Stone referred to as one of the things urgently needed to develop the true value of the prints in the British Museum, but at present in abeyance for lack of funds. When such a catalogue is prepared, it seems to us highly desirable that it should include not only the prints of the National Photographic Record Association, but those also of the other bodies, which in Surrey, Sussex, Essex, Worcestershire, Kent, and Warwickshire, have systematically been accumulating photographs of their respective districts. Possibly some expense-sharing scheme may be promulgated whenever the financial position of the various organisations justifies the publication of a catalogue. The question of copyright in the prints also requires to be considered.

#### PHOTOGRAPHIC RECORD.

BENJAMIN STONE's address at the annual meeting of the National Photographic Record Association last week was of encouragement to those in this country who have set themselves in contributing to the accumulation of the thousand odd prints in the British Museum, or to

## PHOTOGRAPHIC RECORD AND SURVEY.

THE gathering of those interested in the National Photographic Record Association, which took place last week on the invitation of Sir J. Benjamin Stone at the Midland Hotel, St. Pancras, was reported in our last issue, where we gave the text of the annual report of the association as read by the hon. secretary, Mr. George Scamell. In proposing the adoption of the report, Sir Benjamin Stone referred to the continued spread of interest in record and survey work in other lands, and spoke in recommendation of the establishment of a central body, under Government or other national auspices, for the circulation of lantern slides of educational value

among the elementary and secondary schools of the United Kingdom. Sir Benjamin also appealed for the elimination of vulgarity in photography, and expressed the hope that the photographic art would lend its aid in discountenancing the tendencies which lower the art in public estimation. Sir Benjamin Stone acknowledged valuable assistance rendered to the association by Mr. G. Scamell (treasurer), and Mr. George Scamell (secretary). On the proposal of Mr. Philip Norman, seconded by Colonel Sir Robert Rayner, Sir Benjamin Stone was re-elected president, and Messrs. Scamell and Graham were re-elected secretary and treasurer.

### THE MARSEILLES CONGRESS OF PHOTOGRAPHIC RECORD.

THE report of the International Congress, held at Marseilles on October 19 and 20, has now been published. The meetings, which were held under the presidency of General Sebert, adopted a number of resolutions and discussed several papers, the full text of which has not yet been made public. A committee, consisting of the following—M.M. Bing, Bourgeois, Buquet, Casier, Clerix, E. Cousin, Davanne, Fonesca, Caumont, Javary, Lafontaine, Losseau, Colonel Laussedat, Legard, Maes, Otlet, de Potter, Puttemans, Reiss, Taillefer, Colonel Venet, and Wallon—had drawn up a memorandum upon which the discussions of the Congress were based. Among the formal resolutions passed by the Congress are: That it pledges itself to advance the work of photographic record, and to encourage such work among public bodies and institutions of scientific, artistic, and educational aims, to whose assistance organisations undertaking record work may be largely indebted; that the features which should characterise any photograph supplied for documentary purposes

depend on the nature of the subject, but that in all cases the date of reproduction and the date of the photograph should be stated; that the recent decisions of the International Congress of Photography, Liege, 1905, as to the reproduction of manuscripts, coins, seals, should be adopted; that the Congress should collaborate with the Institut Internationale de Bibliographie in reference to the work worked out by M. Richard Goldschmidt for creating and reproducing documents by microphotographic and cinematographic methods.

The Congress also adopted certain resolutions as to the size, of photographs to be preserved. It favoured the steps taken for the preservation of photographic documents by the Société Italienne de Photographie. The Congress further adopted resolutions as to the bibliography of photography, a file of photographic patents, in regard to which particularly it was thought well to consider the offer of the Institut International de Photographie at Brussels as a central organising body for photographic record.

### THE DESIRABILITY OF PROMOTING COUNTY PHOTOGRAPHIC SURVEYS.

A paper read before the British Association.

#### I.—Origin of the Photo-Survey Movement.

THE movement which it is the object of this paper still further to promote had its origin in a meeting of the representatives of numerous local photographic, scientific, and literary societies at Birmingham in 1889, when a paper was read entitled "Notes upon a Proposed Photographic Survey of Warwickshire." This paper was an amplification of the ideas which had been urged in a note upon "The Work of a Local Photographic Society," read before the Birmingham Photographic Society in 1885, and published in the "Photographic News" (Vol. XXIX., p. 421).

Although this Birmingham paper of 1889 had a local title, yet it has, and was intended to have, a general application.

In response to an invitation from the (Royal) Photographic Society of Great Britain, a paper bearing the wider title of a "Proposal for a National Photographic Record and Survey" was subsequently read before that body in London in 1892. In this paper the right and duty appertaining to the "parent" photographic society of taking the lead in this most important work was strongly urged.

Finally, an ambitious attempt was made to link together the photographers of the entire civilised world by an extension of the "survey" idea, and at the World's Congress at Chicago in 1893 a paper upon "The Desirability of an International Bureau, Established (1) to Record, and (2) to Exchange Photographic Negatives and Prints," in which these views were explained, was read and discussed. In this paper three principal points were urged:—

(1) In every country it is desirable that a photographic survey should be initiated. By the term "survey" is here meant a pictorial record of the state of things, physical and general, now existing.

(2) In each country there should be (a) local dépôts (free libraries, museums, etc.) containing complete sets of permanent photographic prints of the immediate district; and (b) a central bureau (in England, the British Museum, for example) containing both negatives and prints relating to the entire country.

(3) Facilities for the exchange or purchase of prints, etc., should be provided.\*

\* A few copies of the first paper of 1889 still remain, and, while the supply lasts, a copy will be gladly forwarded to the secretary of any Society which contemplates commencing photo-survey work. Address: W. J. Harrison, 52, Claremont Road, Handsworth, Birmingham.

On the motion of Mr. Snowden Ward an International Committee was appointed to consider how these ideas might best be carried out. This committee did good work in disseminating a knowledge of the survey movement, and its French representative, M. Vidal, inaugurated a very complete system in his own country.

#### II.—Progress of Photo-Survey Work in Britain.

SEVENTEEN years have elapsed since the photographers of Warwickshire began their task of making a local photo-survey. Each year an exhibition of the Warwickshire survey prints has been held in the Municipal Art Galleries of Birmingham. The prints have been presented to the Free Reference Library, where they have been examined and studied at any time. The number of local photographic prints in the Birmingham library is 3,020 prints, bound in folio volumes.

Other localities where work for the photo-survey has been commenced include Barnstaple, Cardiff, Chester, Darlington, Exeter, Exeter, Manchester, Stoke-on-Trent, Wolverhampton, and Yorkshire; but we have not seen any recent reports of progress in any of these centres. The following, however, are known to be more or less actively engaged in survey work (the names given are those of the hon. secretaries):—

Warwickshire (Geo. Whitehouse); Worcestershire (W. H. Harris); Essex (Victor Taylor); Kent (J. H. Allchin); Surrey (F. F. W. Consett); Yorkshire (P. E. Surtees); Edinburgh (G. Burns); National Photographic Record Association (Geo. Scamell).

#### III.—Objects of Photo-Survey Work.

THE three great objects of the Photographic Record and Survey are to benefit (a) the individual photographer; (b) the scientific photographic societies; and (c) the nation generally.

(a) *The Individual Photographer and the Survey.*—The scheme gives the photographer an object, and we maintain that the work of such a survey is a liberal education for any man, impossible to photograph without learning much about the subject photographed; and the survey brings photographers into contact with experts who are able and willing to afford ample information.

The professional photographers of the British Isles now number a small army, their number being recorded by the census of 1901 at 17,945. Many firms must possess stores of negatives illustrating

"survey" subjects; and it is certain that if properly approached the average professional of any standing would be willing to aid a county photographic survey.

Lastly, there is the great body of "unattached" photographers, whose number can hardly be estimated, but, omitting the casual snapshotter, there are, perhaps, a quarter of a million who could do useful work for a photo-survey if someone would only tell them what to do and how to do it.

(b) *Photographic and Scientific Societies and the Survey.*—The total number of British photographic societies in the list published in the "British Journal Almanac" for 1906 is 354. And in the Year Book of the scientific and learned societies of Great Britain and Ireland for 1905 the number of societies other than photographic, but whose work would be more or less aided by photography, is given as 333. In addition, there are many societies connected with the "fine arts" not included in either of the above lists.

It is a mistake to suppose that the task is one which appeals only to practical photographers. The man with the camera may know how to photograph, but it is impossible that he should always know what is worth photographing. For this purpose he needs the advice of an expert, and the guidance of the man with local knowledge.

To the society, as to the individual, the duty of having a useful public task to accomplish is of great value. It binds the members together, it attracts members, and it brings the society before the public.

(c) *The Nation and the Survey.*—The work of a photographic survey and survey is of value alike to the generation by which it is executed and to all succeeding generations.

The physical features of the land slowly alter, even if left solely to the unaided action of the forces of Nature. There are points on our eastern coast where the sea has advanced a mile or more during the last century. But when we include the agency of man we find yet more rapid alterations. Every year the amount of waste land is diminished—the bogs are drained, the pastures creep up the hill-slopes, forests vanish here, while new plantations spring up there. The opening-up of mines and quarries, the cutting of new canals and railways, the rapid expansion of our towns and cities—in all these, and in many other ways, the natural scenery of these islands continually being changed. Then there are the noble buildings and monuments which we have inherited from our forefathers, and which history is written in stone. Architecture is indeed one of the strongholds of photography.

It is also important that we should record the life of the nation—their trades, the dress, the occupations of the people, their habits, and their amusements. We live in an era of unusually rapid change. The improved means of communication, the discoveries of modern science, and the spread of education all combine to abolish the differences of language, of dress, and of manners.

The British Association has rightly joined in hastening on the work of an ethnographical survey of the United Kingdom; for if

such a survey is not done quickly, the amalgamation of the people of the different counties will have gone so far as to render the task useless, if not impossible.

#### IV.—"District" Surveys and "Subject" Surveys.

The work of a photo-survey may proceed along two distinct lines, although these may, of course, be pursued simultaneously:—

(a) *A District Survey*, where, say, the 1 in. map or the 6 in. map is taken as the unit, and all items of interest within that area are photographed. This is the method so far pursued by those who have approached the task from the photographic side.

(b) *A Subject Survey* in which some definite line of research is followed. It is in this direction that the efforts of most of our men of science who are not connected directly with photography and photographic societies have tended. No praise can be too high for the work of the Geological Photographs Committee of the British Association. The committees on anthropological photographs and on botanical photographs are working upon similar "subject" lines, while many of the other committees largely use photography. Indeed, the British Association seems to be specially well fitted to carry on the work of subject surveys.

#### V.—Base of the British Photo-Survey.

Unquestionably the great unit for district surveys should be the county. For the small working unit nothing can be better than the maps of the Ordnance Survey. The 1 in. map is good; but the 6 in. gives such detail that by its aid we can determine the orientation of buildings, etc., so as to be able to select beforehand the precise hour of the day when the light will be best suited for work.

#### VI.—Promotion of the "Survey" Movement.

What can be done by the Corresponding Societies Committee of the British Association to aid the photo-survey? A small sub-committee might be appointed:—

(a) To collect details as to the work done or being done.

(b) To prepare and circulate printed matter on the work of the survey, so as to make its aims and methods generally known.

(c) To co-ordinate the photographic societies with the literary and scientific societies, so that all may unite in the work of the survey.

(d) To obtain lists of "experts" in various departments who would be willing to advise upon such subjects as photographic methods, processes, and appliances; to draw up county lists of objects and places, specifying their exact points of interest, etc.; to write brief descriptions upon the backs of the mounts, the survey prints, etc.; and to draw up lists of literature upon the counties or other areas.

(e) The publication of series of prints either of districts or of subjects would be one of the best methods of popularising the survey.

W. JEROME HARRISON, F.G.S.

#### Suggestions and Memoranda for the Use of Societies, Committees, or Sections as to the Working of a Photographic Survey.

1. In any district a society, committee, or section may be formed to promote the work of a photographic survey. Such a body may be either independent or part of an already existing society.

2. Members may be of two classes—(a) experts in photography; (b) experts in other branches of science, literature, and art.

3. Members in Class (a) who desire to join in the work of a photo-survey must (prior to election) send in not fewer than — prints of their first contribution to the work of the survey; and must thereafter contribute at least — prints annually. Members of Class (b) must subscribe not less than — per annum.

4. All prints should preferably be by some permanent process, such as carbon, platinum, or bromide, but silver prints will be accepted.

Prints may be of any size. ["Half plate," 6½ in. by 4½ in., or "whole-plate," 8½ in. by 6½ in., preferred.]

5. Prints may be sent in either mounted or unmounted. If mounted, they must be upon "standard" mounts.

These standard mounts may be of two sizes—the first size to carry "whole-plate," or two "halves," or four "quarters"; the second larger size to take prints up to 15 in. by 12 in. Prints must be

mounted behind "cut-out mounts," so that the surface of each print may be protected from abrasion, and they must carry printed headings or labels on their backs for particulars to be filled in by the photographer. The "first size" mounts should measure 14 in. by 11 in., with a central space for the prints of 10½ in. by 7½ in.

6. As many details as possible must be given upon the back of the mount about each photograph, including (1) subject, (2) date, (3) time of day, (4) focal length of lens, (5) printing process, (6) general remarks, (7) contributor's name and address.

7. The officers of the survey shall include a curator, whose duties shall consist of the care, classification, cataloguing, mounting, etc., of the prints; and a secretary, to conduct the correspondence, etc.

[A chairman and a special survey committee may also be necessary.]

8. Beyond simple "sooting," it is not advisable that any "retouching," "improving," or "double-printing" should be done to the negatives from which prints are to be taken, or to the prints themselves.

9. The work of a photo-survey established under this scheme is intended to supplement, and not in any way to interfere with the

work which is already being done in this direction by other photographic or scientific societies.

10. Many districts are not covered by the existing photographic societies; many individuals who are not connected with such societies are willing and able to do survey work, and there are many lines of research which are best conducted by specialists working alone. The Survey General or Central Committee will endeavour to cover such districts and to enlist and direct the services of isolated workers and specialists.

11. Information will be sought as to buildings, places, or regions in which restorations, destructions, or great changes are likely to occur.

Lists of such buildings, etc., have already been compiled by Mr. Snowden Ward and published in the "Monthly Photogram."

12. Lists of special areas for photo-survey work and of special lines of inquiry shall be drawn up and circulated. Suggestions are asked for.

Examples (a) of neglected (or unsupplied) areas such as—

(1) Salisbury Plain, Dartmoor, the New Forest, etc.

(2) The Scilly Isles.

(3) The Fens.

(4) Many isolated districts in Wales, Ireland, and Scotland.

(5) The coast-line generally (to show the effects of erosion).

(6) The Roman roads.

(7) North Lincolnshire (before the development of the recently discovered coalfield changes the entire character of this agricultural district).

(8) The South Staffordshire coalfield—an area where the coal seams will probably be worked out ere the close of another quarter-century.

And (b) of special lines of inquiry, as—

(1) Occupations (trades, etc.) of the people.

(2) Dress as influence—(i) by occupation, (ii) by "fashion."

(3) The native flora of Britain—wild plants photographed in their natural habitats.

13. The survey may hold at least one meeting annually for the purpose either of making a more or less complete photo-survey of some (photographically) neglected or specially interesting district; or of co-operating with some existing society or societies in inaugurating or extending such a survey.

14. Sample sets of mounts, maps, illustrative survey-photographs, etc., shall be prepared. Of these sample sets one set shall be kept for reference at the office of the survey, while the other may be borrowed by any society or member, who must, however, defray the cost of carriage both ways and return the set whenever requested to do so by the hon. secretary.

15. Of the photographs collected, the first complete set shall be deposited in some public institution (preferably the British Museum).

Sets of survey-photographs of local interest may also be presented to any local institutions (as free libraries and museums) which may be willing and able to take proper care of them.

16. If not fewer than — members apply, a special sub-section or sections may be formed, among whom a portfolio of survey prints (with accompanying descriptive notebooks) shall circulate. Such

members shall pay a small annual subscription to defray extra expenses.

17. The inauguration and direction of photo-survey work in the British Colonies may be one of the objects of the survey.

18. Photography at sea, including meteorological phenomena, types of vessels, of seamen, waves, icebergs, marine animals and plants, etc., may be one of the special subjects of which records shall be obtained. Photographs taken by British travellers in unexplored, wild, barren, or savage regions of the earth, such as the Polar Regions, Central Africa, etc., may also be included in the survey collections.

19. An annual exhibition of the work of the survey may be held.

20. The gift of negatives, as well as of prints, is solicited.

21. Local photographic, literary, scientific, archaeological, and artistic societies may be affiliated to the survey. Such societies may aid in the preparation of lists of objects and places for the work of the photo-survey; and by the help of their members as local guides and experts.

22. The survey may appoint a professional photographer or photographers to do the work of printing, both for the survey and for individual members.

23. In any lists of the members of the survey which may be published the number of prints contributed by each member shall be shown (in brackets) after his name.

24. *Apparatus.*—The following specification refers to a set of apparatus which has been used for survey work for several years past:—

(1) Half-plate camera fitted with turn-table and behind-lens shutter; (2) three double plate-holders, with pull-out aluminium slides; (3) three-fold wooden tripod; (4) wide-angle lens (anastigmat), 5½ in. focus; (5) lens (anastigmat) for ordinary work, 8½ in. focus; (6) changing-bag and focussing-cloth combined; (7) spirit level; (8) focussing-glass; (9) yellow screen (for orthochromatic plates); (10) notebook and exposure meter; (11) stiff brown canvas carrying-case; (12) ordnance map of the district. The weight of such an outfit (loaded with six glass plates) will be 14lb.

25. The "half-plate" is, perhaps, the smallest size which gives, itself, a useful print; and yet it is not too big for the enlarging apparatus. Enlargements to 23 in. by 17 in. are to be preferred for wall-pictures.

26. To get good enlargements we must use lenses capable of giving fine definition, and the lenses recommended are most satisfactory in this respect.

27. Plates are to be preferred to films, because of their possessing a plane surface, which can be relied on to be in register with the focussing-screen, and for their rigidity, although films possess the advantages of lightness, non-breakability, and ease of storage.

28. Each member shall be furnished with a ticket or book stating that he is a member of the photo-survey, and giving brief particulars of the survey work. Endeavours shall be made to obtain a reduction of railway fares to bearers of such tickets when carrying photographic apparatus, and also to obtain permission to photograph (as in cathedrals and public places generally) on production of such a ticket.

## PHOTOGRAPHY IN THE WORK OF GREENWICH OBSERVATORY.

The Ninth Traill-Taylor Lecture. Delivered by E. Walter Maunder, F.R.A.S.

It was, I venture to think, a happy idea to institute, in memory of the late Mr. Traill-Taylor, an annual lecture which should deal with new developments, either in the optics or the processes of photography, or take account of its practical application in various branches of science. For these are the very subjects which so greatly interested Mr. Traill-Taylor himself during the forty years in which he was so energetic a worker in the photographic field. As Editor of the *BRITISH JOURNAL OF PHOTOGRAPHY* for a quarter of a century, he made it his business to keep himself and his readers thoroughly in touch with every development of the art, and he was always ready to place at the disposal of the inquirer his own ripe stores of knowledge and experience.

In responding to the high honour of an invitation to give the ninth lecture of this series, I feel that I have not the slightest ability to instruct you upon the two first-named subjects, the optical or the practical developments of photography. But I hope, as I have been for a full third of a century a member of the staff of the Royal Observatory, Greenwich, and am therefore able to speak of certain features of its work from inside experience, that you may possibly feel some interest, as I feel sure Mr. Traill-Taylor would have done in such an account as I can give of the uses to which photography has been put in the work of the Observatory. My own experience of photography is quite narrow, limited strictly to what has been absolutely necessary for my work. But the work of the Observatory

its different departments being of a very special character, and directly or indirectly of high national and scientific importance, I hope that a brief review of the part which photography has played in it will not prove unacceptable to you, nor inappropriate to the present occasion.

Astronomy was the first of all the sciences to make use of the photographic art. At the very first invention of the Daguerreotype process, Daguerre himself, at the request of Arago—then the leading astronomer of France—attempted, in the year 1839, to photograph the moon. But although he gave a prolonged exposure, he only obtained a very imperfect result, the image being very weak and details completely lost. In the following March, however, the great American physicist—J. D. Draper—using a Newtonian reflector of 5-inch aperture, and of 9 feet focal length, obtained a series of Daguerreotypes of the moon by an exposure of about twenty minutes, which showed distinctly the principal features of our satellite. There was, therefore, no tardiness on the part of astronomers to avail themselves of the new process. From its very inception they realised that here they would find a most valuable assistant; how valuable it would prove, however, no one at that early date could even dream.

Draper made a new application of photography, in 1843, when he obtained a Daguerreotype of almost the whole of the solar spectrum. In 1845, Messrs. Fizeau and Foucault succeeded in obtaining a Daguerreotype of the sun, which showed, not only the diminution of light near the circumference, but also revealed some groups of sun spots with their penumbrae.

Greenwich Observatory was not long behind these first experiments in pressing photography into its service. The study of the details of the surfaces of either the sun or the moon was then not part of the Greenwich programme, and hence Airy, the Astronomer Royal, did not follow either of the precedents just mentioned. But, as you all know so well, at the very time that M. Daguerre was working at his process, Mr. Henry Fox Talbot brought out his method of "photogenic drawing," in which paper was rendered sensitive to light instead of a thin plate of silver, as in the Daguerreotype. Here was a much cheaper sensitive surface provided, and one which, from the ease with which paper will adjust itself to the form of any object, was available for purposes to which the silver plate of the Daguerreotype was wholly unsuited. From 1847, therefore, photography has entered largely into the daily work of Greenwich Observatory, and the directions in which it is found to be of service tend continually to increase in number.

There are three chief purposes to which photography is applied in the work of the Observatory at the present time. First, both as to the date of its introduction into the Observatory and the extent of its use made of it, is the continuous registration of the changes in certain instruments; next, the pictorial registration of a great multiplicity of details shown by certain objects at a given time; and third, and often in connection with this registration of details, photography has proved of use as giving the means for the measurement of the position of certain objects, thus replacing direct observations at the telescope. Under the first head, the typical work effected is the automatic registration of the movements of the magnetic needle; under the second, the representation, day by day, of the state of the solar surface; under the third, the great photographic star catalogue.

### Registration of Magnetic Movements.

The original domain, of the Royal Observatory, Greenwich, was limited to the octagonal tower, now known as Flamsteed House, and a little lawn in the rear. But, as the successive Astronomers Royal came into authority, they all extended both the buildings and the area of the Observatory; and Airy, the seventh in the succession, died most. Immediately after his appointment, he obtained the sanction of the Board of Visitors for the creation of a new department—namely, that for magnetic and meteorological observation, and a considerable enclosure was made to the south of the original Observatory, in which a plain white wooden building, cruciform in shape, was erected as the "magnet house." Visitors to Greenwich Park will easily recognise this building, as it stands between the plain buildings to the north, erected by Flamsteed, Bradley, and Airy, and the handsome and imposing structure which the present

Astronomer Royal, Sir William Christie, has built at the southern extremity of the Observatory ground.

This magnet house was the first part of the Observatory into which photography was introduced, for here are housed the various magnetic needles. The needles themselves are very unlike what are generally understood by such a term; they are rectangular steel bars, 2 feet long,  $1\frac{1}{2}$  inches broad, and  $\frac{1}{4}$ -inch thick, and each is suspended by a skein of silk 6 feet in length. The chief needles are three in number: one, the declination magnet, is mounted so as to show changes in the direction of the earth's magnetism; two others, the horizontal force and vertical force magnets, to show changes in its intensity.

The declination magnet, as is very well known, does not point to the true geographical north, but some 16 degrees to the west of it. But in addition to this, it changes its position very slightly during the twenty-four hours. There is a slight movement towards the west every day, from about eight or nine o'clock in the morning to about one or two o'clock in the afternoon; and then a very slow return towards the east, there being very little movement at all during the night hours. The average amount of the movement is so slight that the end of the 2-foot bar, under ordinary circumstances, only moves the thirtieth part of an inch, to and fro, in the twenty-four hours. This daily range, therefore, is of no consequence to the mariner, as it only amounts to about a hundredth part of the distance between two of the points on a compass card, or something like the eighth of a degree.

The method of taking direct eye-observations of the position of the needle at regular intervals would, of course, give a very fair impression of any movement so slow, regular, and progressive as this. And further, it would enable the observer to ascertain whether the amount of this daily range—the amplitude of this daily swing—varied from day to day, from month to month, or year to year. And it was long ago ascertained that its amplitude was greatest in summer and least in winter, and that its average amount is nearly double in some years what it was in others.

When the Magnetic Department was first established, the regular registration of the movements of the magnetic needle was sought to be secured by a system of direct observation every two hours. As the meteorological instruments, as well as the magnetic, were thus read twelve times in every twenty-four hours, it will be seen that this involved a very heavy, irksome, and exacting labour, and was no small tax upon the resources of a staff which then numbered only four persons for this department.

There was no great difficulty in devising means by which some of the meteorological instruments could be made self-registering. The instruments devoted to recording the direction or force of the wind could readily be given that character, for the wind itself supplied a considerable motive power, and it was easy to devise a light apparatus by which it could be made to drive a pencil on a recording sheet. So, too, self-recording barometers have been made in which the pencil follows the movement of the mercury in the barometer tube, or of the face of the vacuum box in an aneroid. A similar mechanical movement has also been fitted to the rain gauge, but all these appliances, however ingenious, are entirely out of place when we come to the magnetic needle. It is impossible to attach to an instrument so sensitive, and which must be so delicately mounted, any train of mechanism whatsoever. The lightest and most free in its running imaginable, would so hamper the needle as to render the record worse than useless.

But a beam of light has no weight, and its impact upon the needle or upon a mirror attached to it, does not hamper or interfere with the movements of the needle in the least. Further, by making the reflected ray travel a greater distance than the incident ray, any desired amount of magnifications might be given to these infinitesimal magnetic tremblings. This was easy enough, but until the advent of photography, it served no useful purpose. The spot of light left no record of its movements on the screen, and direct observation was still required.

Talbot's invention met the exact necessity of the case by supplying a screen capable of retaining an impression produced by the spot of light, and Charles Brooke made a number of experiments on his own account as to the possibility of registering the magnetic movements by means of photography. The process he adopted was not precisely that of Fox Talbot, but was one of the many modifications

brought out in succession to his method. Its introduction is mentioned by Airy in his report to the Board of Visitors for 1847:—

Preparations, however, are in progress, under the direction of Charles Brooke, Esq., for making these magnetometers self-registering by a photographic process. From the specimens furnished by Mr. Brooke, and from the facility with which one of the junior assistants—Mr. Humphreys—has acquired the command of the photographic part, I am satisfied of the practicability of this plan."

In the following year Airy writes again:—

"The declination and horizontal force magnetometers are completely and efficiently prepared, either for observation with telescopes in the ordinary way, or for the self-registration by photographic record, which is now adopted in the daily system of the Observatory. The vertical force magnetometer and the barometer have been very lately fitted up in the same way, and we are now engaged with the petty difficulties which invariably present themselves in the use of a new instrument. The whole of the photographic part has been arranged for us by Charles Brooke, Esq."

It may be added that the same system was applied to the thermometer in the same year, 1848; Sir Francis Ronalds independently adapted photography to the Kew instruments at about the same time that Brooke thus dealt with those at Greenwich.

Seeing that this important step was taken very nearly sixty years ago, and in the early days of photography, it may perhaps be of interest to the Royal Photographic Society to have a full and detailed account of the process, as some of the expressions read a little quaintly at the present day, and the following paragraphs have accordingly been extracted from the Greenwich volume for 1847:—

"The paper used for this purpose is manufactured by Messrs. Lepard, Smith, and Co., of James Street, Covent Garden. It is rather strong woven paper of even texture, and is prepared with great attention to the exclusion of all foreign substances which might combine injuriously with the chemical materials used in the subsequent treatment.

A sufficient quantity of paper for the consumption of three or four weeks is treated in the following manner:—To a filtered solution of four grains of isinglass in one fluid ounce of boiling distilled water are added twelve grains of bromide of potassium and eight grains of iodide of potassium. The solution, either when hot or cold, is evenly laid on the paper with a camel's-hair brush, in such quantity as to thoroughly wet its surface, but not to run off; the paper is then dried quickly before the fire. The paper thus treated is preserved by keeping it in a dry place, and in a drawer.

"When a cylinder is to be charged with photographic paper, the room is darkened, and illuminated only by a candle whose flame is surrounded by a cylinder of yellow glass. The paper is laid flat in an earthenware dish, and is washed with an aqueous solution of nitrate of silver (made by dissolving fifty grains of crystallised nitrate of silver in one fluid ounce of distilled water), which is laid on in quantity not sufficient to run. The paper is then in a state fit to be placed upon the cylinder. When the paper is to be taken off the cylinder, the room is illuminated in the same way, the cylinder is detached from its mounting, the external cylinder is drawn off, and the paper is unfolded and laid flat in a dish. In this state it exhibits no trace of the action of the light. It is then washed with a solution of gallic acid, to which a few drops of acetic acid are added, till it is moderately wet all over; the impression begins soon to appear, and in a few minutes acquires its full strength. The paper is then repeatedly washed with water till the water runs off quite clear. Solution of hyposulphite of soda (formed by dissolving one dram of the hyposulphite in five ounces of distilled water) is then poured upon it, and water is added in considerable quantity; after this has remained about five minutes the paper is washed repeatedly with water. The trace is then securely fixed and light may be admitted into the room. The sheets are then usually preserved for gradual drying within the folds of linen towels.

"The whole of this process, mechanical and chemical, has been arranged by Charles Brooke, Esq.

"The quantity of chemical substances applied in these preparations may be judged from the following statement:—

"Three sheets of photographic paper are employed every day, including in the whole about 440 square inches.

"The amount of chemical substances consumed in three months is nearly as follows:

Crystallised nitrate of silver .....	8 ounces.
Gallic acid .....	3 "
Acetic acid .....	2 "
Hyposulphite of soda .....	16 "
Bromide of potassium .....	2 "
Iodide of potassium .....	1 "
Naphtha (used in the spirit lamp employed for boiling the solutions) .....	½ pint.
Distilled water .....	4 gallons.
Isinglass .....	A small quantity.

"Two gallons of camphine are consumed every week in the lamps and this is the principal part of the current expense of the apparatus.

"Mr. Brooke has found that the light of ordinary coal-gas charged with the vapour of coal naphtha produces as strong a photographic effect as the light of camphine; and preparations are now in progress for introducing gas to the Royal Observatory, to be employed in this manner.

"[1849, August. The gas has been introduced, and, with the vapour of coal-naphtha, is now successfully used for the photographic operations.]"

The method in which the paper, rendered sensitive by the above process, was used, was to roll it round a cylinder to which it was tightly clipped, the axis of the cylinder being placed in the direction of the movements of the spot of light reflected from the little mirror carried by the magnet. Clockwork was then applied to the cylinder to turn it at a regular speed, so that it made one revolution in twenty-four hours, or in any other required period of time, at the end of which the sheet could be taken off and developed. Upon development a blackened line showed where the spot of light had fallen, the line being straight if the magnet had remained immovable but wavering to the right or left if the magnet had moved.

This process was used until 1882, when the introduction of gelatin as a basis in which the sensitive silver salt could be formed rendered it possible to produce a dry photogenic surface, both on glass and on paper far more sensitive to the action of light than had been within the reach of photographers before. The paper which Mr. Ellis, the superintendent of the department, then introduced was the argentic-gelatino bromide paper, prepared by Messrs. Morgan and Kidd, of Richmond, Surrey, and the sheets were developed by means of ferrous oxalate. In 1904, amidol was substituted in the development with good results. The greater sensitiveness of the paper has permitted the effective surface of the mirrors attached to the magnets to be much diminished, and has allowed the use of smaller gas flames. The traces now obtained, therefore, are finer, cleaner and sharper than by the old process, and any loss of register on account of photographic failure is practically unknown.

Two additional details are necessary to render the record complete; a reference or base line has to be provided from which the wandering of the trace can be measured, and a time scale, so that the exact moment at which any movement took place can be ascertained. The former is given by means of a small prism, fixed close to the registering cylinder. This throws on the sensitive paper a beam of light from a second lamp, and this, as the cylinder revolves, traces out a continuous line on the paper, from which the ordinate of the magnetic curve can be measured. The time scale is provided by a clock which at two minutes before each hour interposes a small shutter, cutting off the light from the mirror attached to the magnet. This eclipse lasts for four minutes, and the trace is thus broken by a clearly marked gap, the centre of which corresponds to the exact hour. The introduction of this hourly automatic interruption was due to Mr. Ellis, and greatly improved the accuracy with which time determinations could be made. Previously the light was cut off by hand twice a day. This is still done, so that no mistake can occur in the identification of the specific hours.

The foregoing description relates to the declination magnet, but applies with but little alteration to the traces of the horizontal force and vertical force magnets. The former, indeed, is so arranged that the beam of light from its mirror falls upon the opposite side of the cylinder which takes the register of the declination magnet. Two traces, therefore, are produced on the same sheet, the noon of one trace being nearly above the midnight of the other.

A similar principle is made use of to obtain a register of the

changes in the readings of the barometer, of the wet and dry bulb thermometer, of the intensity of the spontaneous galvanic currents which are almost always discoverable in the earth instruments. In the case of the thermometers, the stems of the thermometers are joined close together, each being covered by a vertical metal plate which there is a narrow slit, so that light only passes through at the parts of the bore of the tube as do not contain mercury; three lines, etched upon the thermometer stems and painted, intercept the light sufficiently to produce a clear and sharp indication on the photographic sheet, the line at each tenth degree being thicker than the other, as well as those at 32deg. and each twentieth degree give it.

It would be tedious to go at length into the details of the records which photography has given us of all the various self-registering instruments used at the Royal Observatory. It would be sufficient to take two of the magnetic instruments, the magnets devoted to declination and to horizontal force.

#### Magnetic Disturbances and their Characteristics.

Direct eye observation was quite competent to show the daily swing of the declination needle, and the variations in the extent that swing with the progress of the year and from one year to another. But from time to time the magnets show movements quite unlike this orderly daily swing. Such "disturbances" may last for hours or even days, and instead of a stately vibration of eight to ten minutes of arc, performed in the course of twenty-four hours, oscillations may be set up each of which it takes only a few minutes to complete, and which may be several times greater in extent than ordinary daily swing.

It is clear that readings of the position of the magnet taken once every two hours are quite incompetent to give any sufficient idea of the real character of these exceptional activities; a great disturbance lasting several hours might be taking place, and yet none of the extreme deflections either to east or west might occur at the time when the observer was at his post. Indeed, magneticians, before the introduction of photographic registration, seem to have had but little idea of the real character of these disturbances, and very naturally relied upon the abnormal readings which they obtained at such times more or less as isolated events.

The first advantage, then, which accrued from the continuous record which photography gave was the manifestation of the actual behaviour of the needle during the progress of a magnetic storm. Here a remarkable feature was at once brought to light. In the first disturbances, and especially in the more considerable ones, the action began with a very sudden and characteristic movement, generally only moderate in amount, but distinguished by its suddenness. This usually appeared simultaneously in the registers of declination, horizontal force, vertical force, and earth currents, the remarkable feature of the movement being its instantaneousness. Before this movement took place the magnets were usually at rest, or so speak more correctly, were manifesting only the usual deliberate oscillation. Then without warning the declination needle would make a sudden movement in one direction, followed by a very quick return. In the more pronounced cases the movement is first very small to the east, then a much more considerable movement to the west, and an immediate return. But in some cases the preliminary westward movement is either too small to be apparent or is omitted.

It would have been impossible for this exceedingly characteristic movement to have been discovered without photographic registration. It would have been yet more impossible to have established—as Mr. Ellis succeeded in doing—the remarkable fact that this movement takes place over the whole world at the same instant of time, within a limit of accuracy to which it is possible to read the registers. The effect is just as if—to use Mr. Ellis's own expression—the earth's orbit had suddenly tripped over an obstacle, and the jar had shaken all magnets the world over.

It is though nearly all the more considerable disturbances begin in this way, yet when we take disturbances of every rank into consideration, those beginning suddenly are by no means in the majority; most of the minor ones begin more gradually, so that it is a question of some difficulty to decide what is exactly the time of commencement. The majority of these, so far from beginning at the same instant all over the world, are evidently dependent in some degree on the presentation of the station towards the sun, or, in other

words, upon the local time. These, therefore, constitute a second order of magnetic disturbances, cosmical in their origin, for they are recorded at widely separated stations, but subject to local influences, as they do not always begin or end at the same moment of absolute time.

Yet a third class of irregularities in the magnetic movements are those which are restricted to small areas of the earth's surface, and tend to recur at the same local hour on two or more succeeding days.

The old method of direct eye-observation could indeed have shown that there were disturbances from time to time; but, being necessarily discontinuous in character, they could never have revealed to us these three different orders, nor the special features which characterise each. These important facts could only be brought out by such a perfectly continuous registration as only photography could supply.

It is much to the honour of Greenwich Observatory that as the result of a convention entered into with the Paris Magnetic Observatory at Parc Saint Maur, it was the first to publish regularly reproductions of the traces of all the more important disturbances year by year. This work, the full value of which we are yet far from seeing, was set on foot by the present Astronomer Royal, Sir W. H. M. Christie, K.C.B., in the very first year of his office, at the suggestion of Mr. Ellis, the Superintendent of the Magnetic Department.

These published registers bring to light a most significant fact. If the times at which the different disturbances commence be collated together, it is seen at once that there is a marked tendency for them to follow one another at an interval not greatly differing from twenty-seven days. Thus, in the year 1886, there were four disturbances in the autumn, and only four, occurring respectively on September 9, October 6, November 2, and November 30. In the following autumn a similar series was noted a little earlier in the year, the dates being August 1, August 28, September 25, and October 22. Yet again, in 1892, there was a very violent magnetic storm on February 13, followed on March 11 by another of very nearly equal intensity; and many other similar instances might be given.

#### Photographs of the Sun's Surface.

There is no necessity for me to illustrate the value of photography in continuous registration by further examples drawn from the work carried on at Greenwich. Let me proceed now to the second division of my subject, the pictorial registration of numerous details. Here the typical work has been that of my own department, the daily photographing of the sun's surface. It will be seen that this is an attempt—so far as the conditions of the case permit—to secure a continuous record of the features presented by the sun. Many of these are undergoing constant change, but if we have a photograph taken on every day we have a record sufficiently complete of all the chief markings on the surface.

Solar photography was not begun very early at Greenwich, as it seemed at first to lie outside the original purpose of the Observatory, and it was considered that the delineation of sun spots and facule should more properly be left to amateurs. But when Schwabe in 1851 demonstrated that there is a regular periodicity in the numbers and areas of spots, and various magnetic observers, such as Gautier, Sabine, and Wolf, showed that this periodicity corresponded to that displayed by the magnetic diurnal range, sun spot observation became a necessary corollary of magnetic work.

Much most valuable work was done by direct observation by Carrington and others, but Rutherford in America, and somewhat later De La Rue in England, realised that this was especially a field in which photography could be of service. In 1857 the well-known Kew photo-heliograph was constructed after designs furnished by De La Rue, and solar photography was carried on with this instrument for several years at Kew. It was then transferred to Greenwich, and in 1873 was placed under my charge. It was a simple and efficient but by no means ornate instrument; the diameter of the object-glass, which was specially corrected, not for the visual, but for the photographic rays, was only  $3\frac{1}{2}$  inches, the focal length being 50 inches. A positive enlarging eye-piece, giving a magnification of about eight diameters, was placed behind the primary focus, and the resulting image was nearly 4 inches in diameter. It was replaced in 1875 by a somewhat larger instrument, constructed by Dallmeyer for use in the Transit of Venus of 1874. This was fitted with a new

enlarging lens in 1884, by which an image nearly 8 inches in diameter was secured. More recently still, in 1890, the late Sir Henry Thompson presented to the Observatory a photographic refractor 9 inches in aperture. This has been fitted with an enlarging lens to give an image on very nearly the same scale as the Dallmeyer photo-heliograph, and is now the instrument in ordinary use, although the Dallmeyer photo-heliograph is still kept in reserve in case, for any reason, the Thompson instrument should not be available. But three other observatories collaborate with Greenwich in order that a record may be secured on days when the sun cannot be observed there, and these each still use instruments of the Dallmeyer model. These three observatories are situated at Dhra Dun, in Northern India, at Kodaikanal, in Southern India, and in Mauritius, and photographs taken at one or other of these three stations are sent to Greenwich to fill up the gaps in the series there.

In 1873 the gelatine film had not yet come to its own, and collodion ruled. The process we employed was one worked out by De la Rue. A collodion iodised by cadmium was sensitised in a neutral bath of silver and developed by pyrogallie acid, one grain to the ounce of water in conjunction with half a dram of acetic acid. The method had some great advantages. The secret of success in every branch of photography is to obtain control over your plate. Usually this means that you must have it in your power to over-expose and over-develop. The difficulty in solar photography is the exact reverse of this. We generally have too much light, and the first object with the solar photographer is to get the power into his hands of under-exposing. The small aperture of the telescope, the very considerable magnification given to the image, and the rapidity of the exposing shutter are all means that it is necessary to employ. But, in addition, it was necessary to use a plate of little sensitiveness, and to treat it with a slow developer. These the process employed supplied, and the grain of the image was remark-

ably fine. The drawback, however, was that in our climate the moments of clear sky and of good definition were by no means a to synchronise with the completion of the preparation of the plate, and many a plate was spoiled before there had been any opportunity for exposing it.

This difficulty led to the adoption, in 1884, of the gelatine plate, which, however, proved too rapid for use under the then conditions. Part of the difficulty was got over by using double magnification, an image of 8 in. diameter being substituted for one of 4 in.; part by the use of very slow lantern plates. The result has been that fair and easily measurable photographs are obtained almost every day when the sun shows itself for a few minutes, and that upon days of really fine definition, details of a remarkable delicacy are brought out. A man at the distance of four miles subtends about a minute of arc, which was about the diameter of the sunspot now thrown upon the screen. I think you will agree with me that, to show this amount of detail in an object no broader than the apparent height of a man four miles distant in a photograph taken with a camera of only 4 in. aperture is a tribute to the definition which we occasionally are favoured with even yet at Greenwich. If in future we can do as much it will be by kind permission of the London County Council.

The first but not the only use made of these photographs is to count up the area of the sun's surface, covered on any particular day by the chief dark and light markings shown on the sun. The dark markings, the spots, are divided into two chief portions, the larger and better defined spots having a very dark central region, surrounded by a fainter or penumbral region. On the average the area of the umbra is about one-fifth that of the entire spot. The faculae, as the bright markings are called, are more extended, and cover on the average about twice as great an area as the spots.

(To be concluded next week.)

## THE MANAGEMENT OF REMBRANDT LIGHTING.

THE term "Rembrandt" lighting was applied by someone at some time who had a very incomplete idea of the special character of many of the portraits produced by one of the greatest of the world's painters. A picture may have a preponderance of shadow, the high lights being few and forcible, or it may have a preponderance of lighter tones with darker notes of emphasis. The greater number of Rembrandt's pictures are characterised by strong shadows, and small areas of brightly lit portions of the subject.\* The photographer when he speaks of a "Rembrandt" lighting, too often thinks of a head turned sideface, with a strong light thrown on the profile, and the rest of the face and figure almost detail-less, a dark solid mass. This is precisely what a "Rembrandt" portrait should not be. Dividing the lightings of a "Rembrandt" character into three sub-headings we may consider full or nearly full-face portraits with a strong illumination from the side, side or nearly side-face portraits, with the face looking more or less towards the source of illumination, and quite side-face portraits in which the whole of the face is in shadow, the profile being outlined only, this style of lighting being sometimes called "line lighting."

There are certain defects common to all these styles which unfortunately exist with only too great frequency. The tendency is to employ much too strong a light, with, as a natural consequence, too great a contrast in the subject. The high lights of the negative are thus fully exposed, and are very dense on development without the shadows being sufficiently exposed. Or, per contra, if the shadows are exposed the high lights are solarised and all proper modelling is lost. Frequently, even if the lighting is sufficiently soft in character, the negative is very much over-developed, and has harsh printing contrasts. Again, the face is usually turned towards a strong light, with the result that the reflexes in the eyes are too large, and need scraping down in the negative, a very critical piece of work, and one calculated to destroy proper expression. Further than this, the strength of the light causes the pupils to contract, and the actual expression is not so good as when the pupils are larger or more dilated.

\* An article on the characteristics of Rembrandt's paintings, by Mr. F. C. Tinney, appeared in the JOURNAL of November 9, p. 885.

### Normal "Rembrandt" Lighting.

Let us see then how these defects may be avoided and how the desired effects may be obtained with the greatest economy of time. Taking the full-face, or the nearly full face portrait first, we place the sitter in the normal position in the studio, and light the head so as to secure a nicely-rounded lighting with soft transparent shadows, keeping the reflexes equal in both eyes. Now place over the head a screen towards the shadow side an opaque head screen, watching carefully the result, which should be that of increasing the area of the shadows, and so conveying the effect of more forcible illumination of the head as a whole. If the original lighting has any tendency to flatness, that is, if there was too much light admitted from the top and side towards the front of the sitter, the blinds here may be closed. If the lighting is the normal 45 degrees from top and front, however, the opaque head screen should do all that is necessary in the way of increasing the area of shadow. Of course, a somewhat dark background will be used, and it may be pointed out that if the background is graduated, the dark portion coming again the light side of the head, and vice versa, the result is to accentuate the effect of contrast, to make the lights more forcible and the darks more rich, while at the same time the actual contrast is not increased, but is kept within the compass of the plate, and the shadow detail will be recorded before the high lights are over-exposed. The moment's consideration will show the worker that this is the principle on which to work, for in the normal full face lighting we have the high lights strong enough, and the shadows dark enough. That is needed for the production of the Rembrandt effect is to get a smaller area of light and a larger area of shadow, and this is more easily effected in the way suggested. It will be noticed that the method pre-supposes the ability to light a head well in what may be called the normal way, and, of course, also assumes that the lighting in the studio is properly under control, and that the studio is not flooded with light from every direction.

Two alternative methods may be given for obtaining this same effect, in each case starting with the normal full-face lighting as a basis. The one method is to turn the head a little further from the light, that is, more towards the three-quarter face position, a

then move the camera further to the side, so as to obtain again a full-face view of the head. The second method consists in bringing the sitter nearer to the camera until the proper effect is secured, and then, of course, drawing the camera back also so as to get the image on the ground glass of the proper size. An objection to both of these alternative methods is that the character of the lighting is more distinctly side-lighting, and this does not give so good a modelling, in some instances conveying a swollen appearance to the cheek or neck.

### Side-face "Rembrandt" Portraits.

We may now proceed to the second type, the head photographed side-face looking towards the light. Again, the simplest method of procedure is to light a full-face portrait in the normal way, taking care that the reflex shows equally in both eyes, but only just in the eye on the shadow side of the head. Now, without moving the sitter, wheel the camera round so that a side or nearly side-face view of the head is obtained, and it will be found that the effect of light and shade is almost if not quite satisfactory. It may be that the shadow will prove a trifle lacking in transparency, and should this be the case a reflector of gray calico may be placed as near the camera

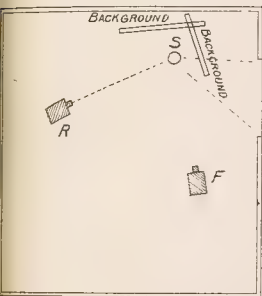

Fig. 1.

Fig. 2.

as possible so as to avoid any danger of cross lighting. If this reflector be a frame covered with canvas, papered white, the device originally adopted by Mr. Henry Van der Weyde may be used, a hole being cut in the reflector on a level with the camera, and the lens then pointed through this aperture. This method gives a soft illumination of the shadows with the risk of cross lighting reduced to the minimum. Of course, this method of obtaining side-face Rembrandts necessitates a studio of considerable width, and as this is by no means a general condition of things, it cannot be so often employed as might be desired. The following method then will be that most generally useful. Open about four feet of side light at the extreme end of the studio, the end occupied by the sitter, and about as much of the top light, taking care that the general angle of illumination is 45 degrees. Avoid too low a side light, which is apt to glare into the sitter's eyes, producing the excessive reflexes referred to, and avoid also too direct a top light, which causes the air to be much too white. If the blinds cannot be arranged without excess of top light a translucent head screen must be used to soften the lighting. Now place the sitter somewhat nearer to the

camera-end of the studio than the open glass, so that the lighting is from the side, but rather behind the sitter. On turning the head towards the glazed side of the studio it will be found that the eyes are not looking to the open glass, but at the curtained portion of the window, and if the photographer places himself in front of the sitter, at P, Fig. 2, getting a full-face view, he will find the lighting is practically a normal full-face lighting. Now, with the camera getting a side-face view of the sitter, and the reflector arranged so that the lens looks through it or just past its edge, a good Rembrandt lighting will be obtained. In order to make this more clear, two diagrams showing the floor of the studio, and giving the positions of sitter, camera, and window, have been prepared. Fig. 1 shows the normal full-face lighting when the camera is at F, and by placing the camera at R, the studio being a wide one, the Rembrandt picture is secured. Fig. 2 gives the positions in the narrower type of studio. The relative positions of glass, sitter and camera in the two methods will be found very similar. It must not be supposed that all that is necessary is to chalk one or other of these diagrams on the studio floor, and then after placing the sitter to make the exposure. Some little modification either in the strength or direction of the light is almost sure to be needed, and, of course, much depends on the character of the face under consideration.

### Line Lighting

We are now left to consider the line lighting, which is, perhaps, the least used of the three types. Only the most perfect and refined profiles will bear this treatment. The effect to be aimed at is a shadow filled with soft delicate detail, while more or less all round the head is a line only of light. On the hair the light will be rather pronounced. To produce this effect the light must be almost exactly behind the sitter, and as the background, if too large or too near, would cut off all the direct light, it becomes necessary to keep it well back from the head, and to use a back light in which top light predominates. Care will be needed to prevent light striking into the lens, and here, again, the reflector, through which the lens looks, will prove a valuable adjunct, for in addition to softly illuminating the shadows, if properly arranged it will prevent any light other than that from the subject reaching the lens. One of the causes of frequent failure when employing this method of lighting is the placing of the model too near to the light. A large dark background at a good distance and the sitter well in front of the light will give the most pleasant effects.

It may not be inappropriate to add a word or two on the development of plates exposed under the conditions considered. A perfect piece of lighting may be spoiled in its rendering if the plate is badly developed. The usual mistake is over-development. These Rembrandt lightings are almost invariably taken with dark backgrounds, and a negative so produced needs less development than one of a normal vignette head, against a light grey background. Either the normal developer may be used and the time of the development shortened by about 25 per cent., or the developer may be diluted by the addition of, say, half its bulk of water, and development carried on for about the normal time. In any case, prints should be carefully examined, and if there is any lack of gradation in the highest lights by the time the shadows are deep enough, it may be taken as an indication to soften the lighting, or if that be sufficiently soft, to keep the negatives less strong in contrast by one or other of the methods indicated.

**CINEMATOGRAPH FRAUDS.**—Another matter which is disturbing the French Service authorities (says the "Globe") is the way in which sailors, naval and military are being brought into ridicule by photographers and by cinematograph operators, the latter being the more serious offenders. Their mode of procedure is to take a motley crowd clothed in uniform into close proximity to a barracks, and there to photograph them in ludicrous pictures of what are styled "military life," to which the barrack walls and the armed sentinels add colour. For the future proceedings of this kind are to be visited with arrest and prosecution.

**THE SOUTH ESSEX CAMERA CLUB'S FIFTH ANNUAL EXHIBITION** will be held on January 24, 25, 26, 1907. There will be four open classes, gold, silver and bronze plaques will be placed at the disposal of the judges in each. Entry forms can be obtained from the Secretary, Mr. J. H. Mitchell, 180, Browning Road, Manor Park, E.

**BARNET Seaside Competition.**—The list of prize winners is as follows:—1st prize, £2 2s., J. D. Ross, Brechin—"Toil." 2nd prize, £1 1s., E. J. Jarvis, Plymouth—"Sailing Barge." 10s. 6d., W. L. G. Bennett, Whyteleaf—"A Derelict." 10s. 6d., J. Bradwell, Ryhope Colliery—"An Autumn Sunrise." 10s. 6d., Miss F. C. Davies, Weston-super-Mare—"A Gambol on the Sands." 10s. 6d., Victor Hey, Scarborough—"Fishing Smack at Anchor." 10s. 6d., W. E. Houghton, Highbury—"What is it Willie?" 10s. 6d., Clarence Ponting, Scarborough—"A Pale Moon through the Mist Arose." Messrs. Elliott and Sons, Ltd., offer their best thanks to all those who entered the competition.

VISITORS are specially welcome at the London and Provincial Photographic Association on November 29, when Mr. D. W. Hart will demonstrate and lecture upon an improved process of development.

## THE FREE PORTRAIT CANVASSERS.

## FIGHTING THE SWINDLE.

IN connection with the canvassing frauds at Perth, the exposure of which in the "Perth Constitutional" we referred to last week, we see that our contemporary has organised a spirited crusade against the canvassers, and in its issue of November 12 has cast a vivid light upon the shady, blackmailing methods employed by the gang. As too much publicity cannot be given to these methods, we make several extracts from our Perth contemporary's inquiry:—

The western side of the city was the first district visited by our representative, and while the canvasser seems to have got a few orders here, in one tenement he visited there were at least three tenants who, having been once bitten, were twice shy. Their experience happened about a year ago, when what they described as "a sweet young lady" called, and under precisely the same inducements, obtained as many as three photographs from one household. A fortnight later the rough proofs were produced, and the price then demanded was 15s. All the blame was thrown on the young lady, who, it was said, had made a "perfect mess of things." Two of the tenants who refused to pay for the enlargement have never received back their photographs. The canvasser on the present occasion made bold efforts to secure an order, keeping the door of one of the houses open by placing his foot in the doorway and insisting on being heard. The company which he represented, he pointed out, had nothing to do with the other firm, and his case was genuine. His firm was to start business in Perth, and they were giving away 200 free enlargements for nothing as advertisements.

In one case the canvasser opened the door and walked right into the house. The party in question had a number of photographs displayed, and the canvasser remarked: "We are just going to give you a present of a photograph." The lady, however, declined, whereupon the plausible canvasser informed her that she did not require to be frightened, as it was just the same as handing in a packet of Van Houten's cocoa. Questioned as to the frame, he assured the lady there was no frame and nothing whatever to pay, the only condition being that she showed it to her friends. A photograph—one much valued—was secured, and the other day canvasser No. 2 made his appearance with the proof and specimen frames. When told that the enlargement was to be free and that the agreement was that the framing could be done by anyone, he ridiculed the idea, and pointed out that it was nonsense to expect that they could work for nothing. The price demanded in this case was 18s., but it was not paid. Almost next door, under the same circumstances, the price demanded was 15s. The mistress of the house said that her husband would never allow her to give a figure like that for a thing that was to be free. "Ah," replied the canvasser, "your husband must be a bit of a Jessie." "You'd better come back and see," remarked the lady. He did go back, and we believe he has since changed his opinion about the husband.

In another instance the lady of the house informed the canvasser that she had nothing worth enlarging. He, however, persisted, and assured her that anything would do. The housewife replied that the only two photographs she had were of the children, and as she did not care much for the cards she would never dream of having them enlarged. Getting hold of a photograph of her little boy, however, the canvasser assured her that it would do splendidly, and that he would send it on to her in ten days. The woman is emphatic that no mention was ever made of framing. The other day the second canvasser appeared with the rough proof and specimen frames. The woman refused to have anything to do with the matter whereupon it is alleged that the canvasser became obstreperous, threatening her with legal proceedings, refusing to leave the house, and ultimately putting the poor woman into such a state of terror that she drew upon her hard-earned savings to meet her rent, and gave him 15s. 6d. In return she received a receipt for 12s. 6d., and on demanding to know why he had charged 12s. 6d. was informed that the other shilling was for his commission. The woman was thereafter informed that the enlargement and original would be sent on, her money being simply a deposit. The attention of the neighbours was attracted to the scene, and although the canvasser had rather a rough time of it, all efforts failed to obtain from him a return of the money. Determined,

however, not to be beaten, the woman followed the man until she met a policeman, but the constable did not consider it was a case coming within his jurisdiction. The canvasser, it is alleged, gave an address which was false, investigation showing that the address was that of a shop.

In the same vicinity a lady was informed she was bound in no way, and, although she made it a point to question the canvasser particularly as to the question of payment or framing, the reply was of such an assuring nature as to call forth the remark from the lady: "Oh, you're a good sort." She gave a photograph of herself and husband, and was very much amused at the surprise she was going to spring upon her husband. Two men called upon her and showed her frames valued at 16s. and 23s. or thereabout. She said she did not want the frame, but was told she must buy a frame or pay 7s. 6d. for the photograph. On remarking that she was informed that the enlargement was to be free, she was practically told she was telling an untruth, and that if she did not pay up she would find herself in the Sheriff Court next week. The canvasser refused to leave the house until paid, and the woman, becoming alarmed at the man's manner, ultimately gave the 7s. 6d. for the photograph.

In one instance the photograph was secured by exhibiting the photograph of a friend of the lady's. The lady was warned by the account in the newspaper, however, and when the second canvasser called he found that, although the lady he had to deal with was young, she was not lacking in courage. "May I come in and show you the picture?" said the canvasser. "No," replied the lady, "you will stay at the door." "Oh, but we never do business with our customers at the door," remarked the canvasser. "All the business to be done between you and me will be at the door," was the reply. "Then," remarked the canvasser, "I won't show the picture." "I don't want to see it," was the answer, "but I want the original photograph back, and I will have it." Baffled by the grit shown by the young lady, the conversation was continued for some time, the canvasser brandishing his stick in a threatening manner in front of the lady's face. As a parting shot, the young lady asked if he had read the "Constitutional," and the canvasser admitted rather ungraciously that he had, and shouted, as he was going down the stair, that the original would be sent back.

The "Perth Constitutional" has learned that the postmen were busy in Craigie district, after the above proceedings, delivering returned photographs. Not only were the photographs very roughly and carelessly enclosed in a small piece of brown paper, and tied with a coarse piece of twine, no precautions being taken to protect the picture from injury, but each person receiving their photograph in this way had to pay the postage.

At Romsey, Hants, itinerant photographers have received a warm reception. Two separate gangs paid a visit to the Hampshire town within the past two weeks. The first came touting for orders for photographs at nominal prices. They had not long commenced operations when (as reported in the "Romsey Advertiser") they were observed and closely pursued by the energetic manager of a local firm, whose work was, of course, not to be compared with that of the visitors. The local man was ably supported by several shopkeepers, whose premises the itinerants commenced to photograph. Their assistants all lined up in front of the shop, and permitted the Romsey man to take a photograph, but when the other camera men proceeded to follow suit the assistants with much merriment disappeared inside their premises, thus frustrating any effort on the part of the strangers to do business. The latter subsequently made with all haste to the railway station, showering severe reproaches on Romsey, and especially its photographer.

The next party to attack the Romsey photographic community numbered eight—four men and four women this time. These were of the "make haste" order, offering to do cheap enlargements of people's "departed friends and others." They divided themselves into two batches, presumably with the idea of "riddling" the whole town and securing as many "victims" as they possibly could. They, however, did not stay long, for, as happened on the previous occasion, they were haunted all around by some of the local photographers with cameras over their shoulders. The local men succeeded eminently in preventing the invaders from fooling the people. The occasion provided considerable amusement to the large crowds in various districts of the town, who watched the proceedings with

interest, and who gave the visitors little, if any, encouragement. The "Romsey Advertiser," which reports these proceedings, explains the fraudulent nature of the canvassing business, and deserves the thanks of both photographers and the public for its exposure of the "free enlargement" swindle.

### THE QUEKETT CLUB DEMONSTRATIONS.

The first of the demonstrations on the practical use of the microscope organised by this well-known club was held on Friday last, and drew a very large audience. The subject was "Illumination," and with the aid of photometers it was shown that, while the broad side of the lamp flame gives more light than the edge, the latter gives more light than a corresponding area of the side of the flame. The microscope was arranged to show the diffraction effects that play such an important part in the theory of the instrument as expounded by Abbe. Others were set up to show the various degrees and effects of illumination, with and without substage and bull's-eye condensers, and with plane and concave mirrors. Also several instruments were arranged to illustrate the fact that the best illumination is obtained when the back lens of the objective is filled with light, while the importance of well corrected condensers was also demonstrated. Photographers are frequently compelled to make use of the microscope, and matters such as those dealt with in these demonstrations are of great importance, but just the very ones that the casual user of the microscope is unfamiliar with. It is no easy matter to obtain good results or even to make accurate observations with a microscope unless one is fairly well acquainted with the proper manner of using it, and faulty illumination may alter the aspect of the subject to such an extent as to give an entirely wrong impression. These demonstrations will practically cover the whole ground, and those who attend them all should be able to use the microscope and all its various accessories to the best advantage, even though their practice is only very occasional. We cannot too strongly advise those who sometimes use the microscope to take the opportunity of profiting by these demonstrations. The remaining five take place on the third Friday in December, January, March, April, and May, and are well worth the half-guinea subscription necessary to become a member of the club. Full particulars can be obtained from the hon. secretary, Mr. Arthur Earland, Reading Villa, 31, Denmark Street, Watford.

## Exhibitions.

### SOUTHSEA PHOTOGRAPHIC SOCIETY.

This society is fortunate in possessing a suite of rooms in which their annual exhibition can be held, and whilst the walls and screens are somewhat crowded, the whole effect is to give one the impression of a very satisfactory show as regards numbers, for, exclusive of lantern slides, there were no fewer than 636 pictures, over 400 of these being in the open classes. When one adds on to these the collection of Herr Dührkoop's pictures, as first shown in the offices of the BRITISH JOURNAL OF PHOTOGRAPHY, there is no question that the visitors will find ample to repay them.

Taking the exhibition on the whole, the average merit, particularly in the large open class, is distinctly high, and it includes many pictures which were shown at Hackney and at the R.P.S. and the London. Obviously the judges were struck, too, with the quality, for they awarded no less than ten plaques and eleven honourable mentions. In the members' classes, the quality of the work was generally very satisfactory, though a few of the members seem to imagine that burying the whole of the print in murkiness and fog—this is particularly noticeable in the portraits—or the use of the coarsest possible grain obtainable by gum bichromate, is the highest form of art. Possibly the judges' awards will disabuse them of these mistakes, however.

The society is to be congratulated on their courage in trying to alter the technical side of photography by offering no less than four bronze plaques for technical prints and lantern slides, and as four honourable mentions were also given it ought to encourage other societies and exhibitors in this direction.

The judges were Messrs. F. J. Mortimer and J. L. S. Mummery for the pictorial, and E. J. Wall for the technical classes, and their awards were in the open classes as follows:—

A.—Pictorial: Plaques to Rudolph Dührkoop, "Study"; J. C. Richards, "Portrait"; L. J. Steele, "Garden of Allah"; J. C. Batkin, "A Rift in the Fog"; A. Marshall, "His Daily Bread" and "A Venetian Pearl"; S. G. Kimber, "A Relic of the Past"; H. Colebrook, "Old Shoreham"; Brenda Johnson, "Summertime"; Dr. E. G. Boon, "The Injured Butterfly." Hon. Mention: R. Burnie, "Gooseberries"; A. G. Thistleton, "A Confidential Chat"; S. L. Neame, "The Suppliant"; W. A. J. Hensler, "Sunbeams"; E. T. Holding, "The Nation's Pictures"; W. A. Clark, "Triforium, Gloucester"; E. O. Hoppe, "Adagio"; J. D. Johnston, "In Normandy"; S. G. Kimber, "A Sunlit Cloister"; W. M. Post, "The Beaver Dam"; Miss Marillier, "Japanese Peonies."

B.—Technical: Plaque to W. Farren, "The Home of the Missel Thrush." Hon. Mention: Mrs. Veley, "Male, Meerkat"; J. Vandel, "Gooseberries."

C.—Pictorial: Plaques to E. R. Bull, "A Haven of Peace"; A. G. Thistleton, "A Confidential Chat." Hon. Mention: W. A. I. Hensler, "A Bye-way"; Ellis Kelsey, "The Rescue."

D.—Technical: F. Ward, "The Roach"; W. Farren, "Sunshine on Glebe Plumage"; S. A. Pitcher, "A Flower Study." Hon. Mention: D. H. Hutchinson, "Development of the Hair"; G. A. Booth, "The Emperor Moth."

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents were made between November 5 to November 10.

PRINTING APPARATUS.—No. 24,851. Improvements in photographic printing apparatus. Benjamin James Hall, 41, Castlenau, Barnes.

PRINTING FRAMES.—No. 24,884. Improved photographic printing frame. James Walker, 100, Wellington Street, Glasgow.

REFLEX CAMERAS.—No. 24,889. Improvements in reflex cameras and the shutters therefor. Robert Ballintine, Arthur Ballintine, Hew Ballintine, and John Linstrum, 37, West Nile Street, Glasgow.

COLOUR PHOTOGRAPHY.—No. 24,893. Improvements in the taking of negatives for colour photography. John Douglas Ritchie, 154, St. Vincent Street, Glasgow.

CINEMATOPHONES.—No. 24,952. Improvements in bases or supports for cinematographic apparatus. Leo Kamm, 27, Powell Street, Goswell Road, London.

CINEMATOPHONES.—No. 24,993. Improvements in safety shutters for cinematographs. Leo Kamm, 27, Powell Street, Goswell Road, London.

PLATE WASHERS.—No. 24,974. Improvements in washers for plates, prints, etc. Albert James Van Hoorn, 32, Connaught Mansions, Brixton, London.

PLATE CARRIERS.—No. 25,084. Method and apparatus for exposing sensitive layer-carriers. Optische Anstalt C.P. Goerz Actien Gesellschaft, 31, Bedford Street, Strand, London.

FILMS.—No. 25,188. Improvements in photographic films. George Goodchild Stevens and Thomas James Stevens, 33, Cannon Street, London.

SHUTTERS.—No. 25,335. Improved photographic shutter. Walter William Fiddes, 40, Chancery Lane, London.

DEVELOPMENT VESSELS.—No. 25,375. Improvements in vessels for development and other photographic operations. Alfred Blackie, 52, Chancery Lane, London.

PLATE HOLDERS.—No. 25,394. Improved means for carrying photographic plates or films before, during and after exposure, in the camera. Iford, Ltd., and Bertram Vincent Storr, 8, Quality Court, Chancery Lane, London.

COLOUR PHOTOGRAPHY.—No. 25,399. Improvements in cameras for taking polychromal photography. Otto Bauer, 61, Chancery Lane, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**PRINTING FRAMES.**—No. 22,366. 1905. The invention is for a frame permitting of the negative being placed in different positions in relation to the paper. As stated in the claims, the back is adjustable in relation to the front or main frame, wherein it is adapted to be moved or adjusted longitudinally and vertically, and in opposite directions at the opposite ends on the front frame, the back having an opening or space adapted to receive and hold the paper or surface to be printed upon. There is a main frame *a* having slots *b* at one or two ends or sides, and a movable back *c*, with an opening or recess adapted to receive and hold the paper or material to be printed on, and having at its two ends *c'*, slots which are adapted to lie transversely to the slots *b*, and the front

and back parts being adapted to be clamped or fastened together. Bars as *a*, *a'*, are adapted to slide one upon the other, the frame bars *a* being fastened together at their opposite ends by an end piece *a'*, and having a longitudinally adjustable or sliding back *c*. William Lawrence Parkinson, 3A, Imperial Chambers, 62, Dale Street, Liverpool.

**COLOUR PHOTOGRAPHY.**—No. 12,235. 1906. The invention relates to light filters for one exposure direct colour photography with ruled screens, and is intended to permit of such "damping" screens being adjusted to the variations in panchromatic emulsions. The screen comprises two parallel glasses, each being tinted from transparency to a very deep colour shade, the transparent portion of one glass being opposite the deep shade of the other. The glasses are adapted to be displaced parallel to each other, and

Fig. 1.

they are both arranged close up to the diaphragm for the purpose of absorbing an equal number of rays from each bundle of rays.

The screen is made up preferably of two plane-parallel glasses, *b*, *c*, one placed on each side of, and in close proximity to, the diaphragm *a* (Fig. 1), the reason for placing them here being that by this means all the rays forming the image pass through the same absorption field, which would not be the case if it were placed in front of or behind the lens.

The glasses are considerably larger than the diameter of the largest diaphragm of the lens. The one *b* has a portion of its surface white or uncoloured, and the rest is coloured pink, which gradually increases in intensity (Fig. 4). The other *c* has a

portion of its surface white or uncoloured, and the rest coloured yellow, which gradually increases in intensity.

A rack and pinion, *e*, *f*, enables one to move within the lens opening any desired part of the screen, an index *g* indicating its exact position. By using this system any desired amount of colour can be absorbed from the green image and from the blue image, so as to reduce their exposures to the same unit of time as the red image, which is usually the slowest.

Fig. 2.

Fig. 3.

By having only the uncoloured parts of the glass in the lens opening, the lens can be used as in ordinary photography. By moving more or less of the yellow screen in the lens opening, any desired amount of the absorption can be had, as in orthochromatic photography.

Instead of using a screen on which the colour is graduated in intensity, one can make use of a screen, one half of which is uncoloured, the other half coloured with a uniform colour as in Fig. 2.

Fig. 4.

This is a very convenient form, as it is possible to regulate exactly the proportions of the coloured and of the uncoloured portions of the screen within the lens opening. This is very useful when diaphragming.

Fig. 3 shows a screen having colours on its entire surface, but gradually increasing in intensity. Charles Louis Adrien Brasseur, No. 10, East 15th Street, New York, U.S.A.

**SHUTTERS.**—No. 6,512. 1906. According to the invention, the two blinds of a focal plane shutter are each connected at one end to a spring roller, the tension of the spring in which can be varied according to the rate of exposure desired. At the other end the blinds are connected to independent rollers or pulleys mounted upon a common axis, these rollers having arranged in connection with them gearing for winding the blinds and holding them in the desired position, the said gearing having in connection with it a clutch so arranged that when one blind has been pulled up to the required extent the roller carrying the same will be thrown out of action by means of the clutch, whilst the movement of the top blind can be continued until the desired aperture between the blinds is required.

For releasing the shutter for time exposures a revolving stop is provided, having in connection with it a detent lever to oppose the revolution of the stop, and a cushion spring for minimising the shock when the motion of the stop is checked by the detent lever. Alfred Woods, 5, Richmond Park Road, Kingston-on-Thames.

**SUICIDE of a Secretary.**—Last week Mr. Harry Montague Chadwick, secretary of the Equatone Photographic Syndicate, Ltd., was found dead at the office, 34, Knight's Hill, Norwood. At the coroner's inquest the doctor stated that the death was due to taking cyanide of potassium, and the jury returned a verdict of "Suicide while mentally deranged."

## New Books.

"Nature's Carol Singers." By Richard Kearton. London: Cassell and Co. 6s.

Children and all lovers of birds will welcome another "nature" book, owing its existence to the pen of Mr. Richard Kearton and the camera of his brother Cherry. Photographers, too, ought to feel the satisfaction from the fact that the publication of "Nature's Carol Singers" reduces by one the problems of Christmas presents, since it provides a gift book which a boy or girl will value, not only for its pretty photographs of birds, but for the story of their manners and customs which the author pleasantly narrates. The volume is handsomely produced in a green and gold cover, is printed in two colours, and contains a photographic frontispiece.

"The Transactions of the Optical Society for the Session 1904-5" have been published (10s.), and are purchasable, we suppose, by members at the society's offices, 20, Hanover Square, London, W. The volume (of 94 demy octavo pages) contains papers on "Direct Stereoscopic Projection," by Theodore Brown; "Measurement of Absorption of Tinted Glasses," by L. W. Phillips; "Early Literature of Optics," by the President (Professor Sylvanus P. Thompson); and on "The Nature of Vision," by A. J. Bull.

The official catalogue of the Photographic Exhibition held at Berlin during the summer has been issued from the publishing house of Herr Gustav Schmidt, Berlin, W. 10, and may be of service to exhibition secretaries anxious to discover new workers. The usefulness of the volume, however, is curtailed by the omission of any addresses of the exhibitors, beyond the name of their town. The catalogue contains a number of half-tone reproductions of photographs shown in the pictorial section.

## New Materials.

Gaslight Papers—"Portrait Matt" and "Portrait Carbon Surface." Made by Ilford, Ltd., Ilford, London, E.

In respect of two new brands of gaslight paper, newly issued from the Ilford factory, we have to report most favourably. In sending them to us for review the makers gave us no further information than that they were designated "Portrait Matt" and "Portrait Carbon Surface." We soon discovered, however, on proceeding to make prints, that a notable characteristic of the papers is the fine black line obtainable, as intense and as pure a black as we ever remember seeing in a gaslight or bromide paper. Our prints were developed with no formula specially recommended by the maker. We were, in fact, using some "White-Band" metol hydroquinone cartridges which we had at hand, and the negatives were as different as it is possible to imagine, one a view of an open street with a stretch of light foreground, and chiefly consisting of light tones; and the other a portrait against a perfectly black background. The latter is a severe test of a paper, yet the range of gradation in the heavy shadows, as well as in the high lights, speaks eloquently for the capabilities of the paper. The papers are fixed in a plain hypo bath, which, in our experience, is all that is needed to secure stainless prints. The surfaces of the two papers, the semi-gloss of the "carbon," and the not too rough of the "portrait matt," are eminently suitable for average professional work, and we anticipate the entrance of the papers into the high favour of printers, not merely on the ground of their convenience and rapidity, but for the admirable results obtainable.

Pluto "Tintona" Papers. Made by the Leto Photo-Materials Company (1905), Ltd., Rangoon Street, London, E.C.

Three new variations of the cream crayon Pluto collodion paper, which we recently noticed in these columns, have been issued by the Leto Company at the same prices as that material. The papers are "Steel Grey," "Blue," and "Green," these names serving fairly well to describe the colours of the support, the texture of which in each case is rather coarse, and recommended therefore for medium and large size work. The colour of the steel grey paper we like particularly, but we imagine that effective use will be made of the two other colours, which are considerably stronger than the

grey, and hence tend to results of greater softness. All three brands are issued as postcards, and the series is also put up in shilling packets of any given size, containing an assortment of the grades. The paper is toned and otherwise treated exactly like the Pluto C.C. paper.

BARNET Christmas Postcards.—Messrs. Elliott and Sons, Ltd., Barnet, have introduced a fresh series of motto postcards. The decorative portion (on the address side) is by Mr. Charles E. Dawson and embodies such seasonable sentiments as "With 1907 Good Wishes for the New Year." The cards are issued as P.O.P., self-toning, gas-light, and bromide.

CHRISTMAS Card Mounts.—Since our mention of their new catalogue of these mounts a week or two ago, Messrs. Houghtons, Ltd., have sent us a selection of the mounts themselves, from which we see the choice variety offered for all classes of photographers. The striking effects obtainable by aerograph decoration are conspicuous in a number of them, and should induce those who are familiar with this class of work to apply to Messrs. Houghtons for terms. The list gives a very fair idea of the designs, though it cannot do justice to the brilliant colouring and fine textures of a number of the mounts.

## New Apparatus, &c.

The Flashmeter Sold by Houghtons, Ltd., 88-89, High Holborn, London, W.C.

Messrs. Houghton are issuing, under the above title, a flat circular case taking a quarter-ounce coil of magnesium ribbon, and providing for its convenient withdrawal in short lengths. The case has a 2-in. mark on it for the measurement of the ribbon, and a clip in which the detached piece of ribbon is held to be burnt. The "Flashmeter," loaded with a quarter of an ounce of ribbon, is sold for sixpence, the price of the ribbon only, so that, as Messrs. Houghton point out, the measuring case is obtained for nothing. We can testify to the extreme usefulness of the little piece of apparatus, for we have had an identical device, issued a year or two ago by a plate-making firm, in almost daily use.

The "Record" Combination Enlarger and Easel. Sold by W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.

In this apparatus Messrs. Butcher have provided an apparatus which should appeal very strongly to the amateur worker for the reasons that, first, the apparatus folds up compactly when not in use, and, secondly, that the adjustments for enlargements to various sizes are marked on the baseboard in a way which leaves the user nothing to do except to set three pointers to three points on the scale when the enlargement will be in practically sharp focus. He has then only to give a turn either way to the focussing pinion to satisfy himself that the definition is as he desires it. The com-

plete apparatus includes lantern (for incandescent gas, limelight, or oil), negative stage with removable panel to take the negative, scaled baseboard with rack and pinion movement for the front, and marked easel with sliding clamps to hold the bromide paper flatly for exposure. The condenser frame, also, is detachable, so that this part of the optical system is instantly removable for cleaning. The whole apparatus is automatically squared up on erecting it in the ordinary way, and should ensure correct enlargement from the negative. In quarter-plate size without objective, and with easel taking paper up to 15 by 12, the price is £5 or £6 7s. 6d., with objective and scaled baseboard as above described. In half-plate (to enlarge up to 23 by 17) these prices are £8 10s. and £10 12s. The purchaser's own lens may be scaled at a cost of 7s. 6d.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

No.	Name of Society.	Subject.
23	Slough Photo Society	"Latest Kodak Productions."
23	St Albans Photo. Society	"Telephotography." C. P. Goerz.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held November 20, Mr. J. C. S. Mummery, vice president, in the chair. Mr. Alfred Cheese delivered a lecture on "Italy, Past and Present," in the course of which he described Rome, Florence, Milan, the Italian Lakes, and other scenes from ancient and modern Italy.

### SOCIETY OF COLOUR PHOTOGRAPHERS.

A MEETING of this society was held on the 14th inst. at the offices of the BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Mr. E. J. Wall in the chair. The rules as published on p. 849 were adopted without alteration, and considerable discussion then ensued, particularly as regards the circulation of specimens. It was finally decided that portfolios of

prints should be circulated, and also boxes of transparencies, and that the latter should only be sent regularly to those who applied for them, thus practically splitting up the members into two classes of workers, for it was pointed out that possibly the print-maker would not be interested in transparencies, and vice versa. Messrs. G. E. Brown, F. T. Hollyer, A. J. Newton, and E. J. Wall, with the secretary, H. J. Comley, Surrey House, Stroud, Glos., were appointed as the committee of management for the first twelve months.

PLYMOUTH PHOTOGRAPHIC SOCIETY.—Lecturettes formed the programme at the last meeting, and the result quite justified the experiment, for the subjects handled proved interesting and instructive even to some of the members whose experience was by no means short, and the discussions and questions put helped the juniors very much. Mr. E. G. Turney dealt with "Lenses." Mr. W. Annin showed the toning of Velox prints to a brown and sepia tint by the sulphide method. In the discussion several complained of blistering in the washing, and a member said he had avoided this by diluting the strength of the sulphide solution, and after a rinse by passing the print through an alum bath for a short time before washing. He had not further trouble from blisters after adopting this method. Mr. S. H. Tremayne dealt with "Single Lenses (Anastigmatic)," and showed some very excellent lantern slides, which included exterior and interior architectural views of great merit. The work had been done with an ordinary guinea camera. Mr. F. Johnson, in illustrating the subject of "Exposure" with some very fine slides of varied and difficult subjects, contended for the use of an exposure meter, and in this he was supported by the views of other members.

CROYDON CAMERA CLUB.—Mr. Manly, on "Ozobrome," drew a crowded attendance on the 14th inst. Inasmuch as full details have already been given in these pages, there is no necessity to recapitulate them here. It would, however, be unjust to Mr. Manly if we were not recorded that all present formed a most favourable impression of the almost magical, non-reversed, carbon process, both on account of its simplicity in working and the beauty and undoubted permanency of its results. The interest aroused was evinced by the thorough, yet kindly, cross-examination on all points Mr. Manly was subject to, and in which he more than held his own, although he fell a victim to a mild practical joker, who handed up a platinum type print (masquerading as a "bromide") to be operated upon which stubbornly refused to ally itself to the new-comer. "Can I," said one member with perfect gravity, "execute handwork on bromide print, and obtain an Ozobrome therefrom?" "You can," replied Mr. Manly with equal gravity, "not only one, but several," and the first Ozobrome will probably clear your print nicely for you removing the handwork at the same time." Irrespective of the question asked, if a first print by any chance did not reach expectations, a second would most likely fulfil them, owing to the preliminary removal of dirt. A hearty vote of thanks was accorded Mr. Manly.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—"Figure Studies" was the subject of a lecture by Mr. E. H. P. Hillsworth on the 19th inst. As to the best place for obtaining suitable models, the lecturer recommended a fair-sized village, at least fifteen or sixteen miles from London, preferably where there is a bad train service, or no railway at all in the vicinity. There the picturesque rustic may be met "pure and undefiled." They will, as a rule, be most accessible in the proximity of the village tap. Prospective "studies" should always be approached in a friendly and tactful manner, so that their interest and sympathy may be gained. Without this successful work is impossible. In posing, the high light should always be on the head or shoulders of the model, and all the other lines in the picture should lead up to this. Avoid scattered high-lights, such as made by paper, boxes, baskets, curtains, etc., as you would poison, and when these must be included they must be toned down if the best effect is to be obtained. Mr. Hillsworth deprecated the use of a hand camera, and recommended a half-plate camera on a tripod, as by far the most satisfactory instrument for this work. He himself invariably employed an ordinary plate of medium rapidity, well backed. A dilute developer should be used to ensure a soft result full of gradation and half-tones.

SOUTHAMPTON CAMERA CLUB.—Mr. Arthur Marshall, of Nottingham, lectured on Monday evening last, his subject being "Some Dutch Pictures." There was a crowded attendance to meet one who has attained such success at the Southampton exhibitions, and a delightful

last evening, was spent. Mr. Marshall began with a very excellent series of slides, portraying the evolution of a smile in a charming little Dutch maiden, whose change of feature up to the final result was excellently rendered. Then came a long series of the typical Dutch fishermen, whose enormous stature, approximating in quite normal cases to seven feet, came as a complete revelation to the majority of those who regard the Dutch as normally a puny race. The habit of demanding payment for posing led up to the remark that the country was quickly being spoiled as an artist's paradise by the visitors, and stories were told of the hostility on the part of Elberfeld, are delivering the spun thread to the Cerafirm Gesellschaft, and are also themselves partners in the undertaking, whereby a guarantee is secured that no material will find its way into the hands of competitors. It seems certain, however, that the incandescent gas light industry has scored a new triumph, since the only drawback of this brilliant and cheap system of lighting, the great fragility of the incandescent mantle, has now been finally overcome.

THE PHOTO-SECESSION.—An exhibition of photographs by members of the Photo-Secession is to be held at the "Little Galleries," 291, Fifth Avenue, New York, until December 30. The collection, numbering 83 prints, includes contributions by Mrs. Kasebier, Eduard J. Steichen, Clarence H. White, J. T. Keiley, and A. L. Coburn, with one or two—apparently new work—by Alfred Stieglitz. We hope these prints are a sign that Mr. Stieglitz is finding leisure from his labours of organisation to take up his photographic work.

PRIZES for Photographs at the Dublin Zoo.—At a council of the Royal Zoological Society of Ireland last week, regret was expressed at the absence of response to the Society's offer, each year, of a silver and bronze medal for pictures taken in the Society's garden during the year. The competition is advertised every spring in the daily press, but apparently, amateur photographers are not thereby made aware of the existence of the medals. All particulars can be had from the Hon. Secretary (Dr. R. F. Scharff), to whom letters may be addressed at the Zoological Gardens, or at the Museum, Dublin.

BOLT COURT LECTURES.—The programme of lectures to be given at the London County Council School of Photo-Engraving and Lithography, 6, Bolt Court, Fleet Street, E.C., is now obtainable. The first lecture was to have been given last evening in the shape of an address by the Principal, Mr. A. J. Newton, on "Commercial Considerations in Photo-Engraving." Other lectures of special photographic interest are:—"Ferric and Heliographic Processes," by Mr. B. J. Hall; "Photographic Printing in Natural Colours," by Oliver S. Dawson; and "Powder Processes in Photography," by E. W. Foxlee. Admission to the lectures is obtainable free on application by letter to Mr. Newton.

M. ANTOINE LUMIERE.—Our readers will join us in congratulations to the well-known house of A. Lumière and Sons, of Lyons (whose English representative is the Lumière North American Company), on the notable honour which has been conferred on it by the promotion of its founder and head, M. Antoine Lumière, to the grade of Officer of the Legion of Honour. He was appointed Chevalier of the Order some 12 years since, but it is rare for civilians to receive the higher honour of Officer. It is conferred in the case of Monsieur Antoine Lumière in acknowledgment of the great advance made in photography (chiefly in the natural colour branch) by the firm of which he is chief.

PHOTOGRAPHY as a Crime Detector.—That necessity which impels invention has led in Germany to an application, as ingenious as it is novel, of photography to the purposes of crime detection. A merchant of Adorf had been the victim of a series of burglarious entries to his offices, a considerable sum having been on each occasion stolen from his safe. As all ordinary methods of detection yielded no results, he at last improvised a device of his own. It was a combination of electricity with photography. Installing a photographic apparatus in a position that should be favourable without attracting too much notice, he placed it in electric communication with the safe, in such a way that the opening of the door would remove the screen from the camera, and an instantaneous photograph of the person causing the disturbance would be pretty certain to result. The event answered all expectations. One morning the merchant entered his office to find his safe rifled, and a very nice photograph of one of his junior employees in the camera. Confronted with this damning proof of his guilt, the young fellow, after attempting some confused exculpation, broke down and made a clean breast of it. He has just been sentenced to a term of imprisonment by the court at Plauen.

THE Isle of Wight Photographic Society will hold its fourth annual

## CATALOGUES AND TRADE NOTICES.

Mattos, Ltd., 50, Abchurch Lane, London, E.C., has issued a new list of its manufactures which is worth procuring, if only to see an example of beautiful printing. The catalogue is a good example of the sort of thing which a professional photographer might choose to sell his wares. That it lists the well-known varieties of Mattos paper, silk, and wood should be an additional inducement to acquire it.

The Vanguard Manufacturing Company, Maidenhead, true to its title, has already issued its 1907 list, containing the full description of its various chemical products for amateur and professional use.

A revised price list of trade work reaches us from Messrs. Hutchinson and Avery, George Street, Hove. It specifies the various lines undertaken by the firm, in addition to their specialties, of sepia bromides, platinum and carbon, and dry mounting.

MESSRS. ELLIOTT AND SONS, LIMITED, Barnet, send us a very striking show-card, 9in. by 20in., advertising their bromide paper. The subject is a profile portrait study by Mr. Cruwys Richards, and the effect is picturesque. Messrs. Elliott will be pleased to send their autumn set of showcards to any dealer to whom they may have inadvertently omitted to have forwarded one previously.

## News and Notes.

PHOTOGRAPHIC Society for Chelmsford.—We are informed that a committee, pro tem., has been formed with the object of starting a Photographic Society for Chelmsford and the neighbourhood. The arrangements are in the hands of Mr. H. J. Hagon, of Broomfield.

NEW Incandescent Mantles.—The "Times" in its "Engineering Supplement" of November 14, gives a number of particulars of a new mantle for incandescent gas of greatly enhanced strength, and therefore of much longer life. The mantles, which are made under Plaisant's Germant Patent (No. 141,244), consist of a base of artificial fibre, which, as in the mantles hitherto employed, is impregnated with thorium and other salts. The new process consists in spinning artificial threads made from the manufactured cupric oxide and cellulose, and knitting the fabric for the mantles in the ordinary way. These mantles are subsequently impregnated as usual with the thorium salts, and after drying are placed in a bath of ammonia, or better in one of hydrogen peroxide. This last bath is the essential point of the invention, as it converts the previously soluble salts into insoluble compounds—i.e., hydroxides. Since hydrogen peroxide only transforms the salts of thorium into an insoluble state, it is necessary to make use of a cerium bath, after the hydrogen peroxide treatment, in order to give the mantles the necessary 1 per cent. of ceria. It is well known that the mantle owes its great illuminating power to the small proportion of ceria, which lies between the limits of 0.9 and 1.1 per cent.; anything above or below this quantity is detrimental—even an excess of 0.1 per cent. adversely affects the lighting power, and injures the colour of the light. Like most inventions of great general importance, the new process has also been anticipated, since it was known that artificial threads could, like those of vegetable origin, be impregnated with the mineral salts (the nitrates of certain rare earths, thorium, cerium, etc.), and it was likewise known that cupric oxide cellulose threads were adapted for

exhibition at Newport on January 31—Feb. 1. There will be three open classes for pictures, and one each for postcards and slides. A gold medal will be given for the best picture in the open classes, also silver and bronze medals, and an additional silver medal to the exhibitor showing the best average exhibit (not less than three pictures), which may be in the same or different classes. The secretary is Mr. H. G. Morgan Hobbs, "Sunnyside," Watergate Road, Newport, I.W.

## Commercial & Legal Intelligence.

**PHOTOGRAPHS of "The Bondman."**—The suit of the Dover Street Studio Company v. Hall Caine, the Associated Newspapers, Ltd., and the Ballantyne Press, Ltd., which was due for hearing in the Chancery Court to-day, has been withdrawn, a settlement having been arrived at to the mutual satisfaction of all parties concerned.

**TELE-PHOTOGRAPHY.**—J. W. Lynn, an entertainer, of Bedford Park, a son of the late Dr. Lynn, the famous conjuror and entertainer, came up for his public examination at Brentford Bankruptcy Court yesterday. He said he had spent £400 in making models for an invention, which he had not perfected, and that model he had left with the Bishop of Bloemfontein in consideration of a loan of £10. The invention was one he brought out about the time of the Marconi invention, and its object was to transmit a photograph a distance of, say, a thousand miles. The examination was concluded.

At the Basingstoke County Court last week Mr. Wills Chandler appeared for the plaintiff in the case of J. E. Turner v. Alfred F. Rowe, which was a judgment summons for the recovery of 15s. for photographic requisites supplied. The defendant is a photographer living in a private house in Basingstoke, and Mr. Chandler stated "he goes round to all the large houses, takes photographs, and gets the money in advance." He gets orders both locally and in Berkshire, and the goods were supplied to him in the way of his trade." His Honour made a committal order for seven days, to be suspended on payment of 5s. a month.

**ALLEGED Libel by Cinematograph.**—An interesting case, involving a point as to an alleged libel by means of cinematograph pictures, was heard before Mr. Justice Warrington in the Chancery Division on Friday last. On October 29 John Palmer, the well-known Newcastle pugilist, met Gunner James Moir at the National Sporting Club in a twenty-round contest with 6-oz. gloves for the heavy-weight championship of England. Palmer was beaten, and he now asked for an injunction restraining the Club from exhibiting cinematograph pictures of the fight. Mr. Rowden, K.C., for Palmer, said that the proposition of law involved was as to how far an unauthorised photograph tending to bring the subject of the photograph into discredit should be reproduced, and his contention was that upon that proposition he was entitled to ask his lordship for the injunction. In his affidavit Palmer said that before the fight he protested against the preparations which were being made to take pictures, and subsequently wrote to the defendants to the effect that the threatened reproduction would be calculated to do him much damage and cause him much personal annoyance and indignity. The defendants' case was that Palmer never protested, and that he knew very well that the pictures were being taken, as the working of the apparatus was accompanied by the usual "clicking." Counsel said he had never been in his client's position—(laughter)—but if he had been, he was sure that all his attention would have been concentrated on his opponent, and that he would never have noticed the clicking. (Laughter.) His argument was not based on copyright; his contention was that there was no right in this country to reproduce an unauthorised photograph which tended to bring the subject of it into disrepute. Without calling upon the other side his Lordship said that to obtain relief Palmer must base his case on the ground of libel, which in fact he did. He was not satisfied, however, on the evidence before him that these cinematograph pictures constituted a libel at all. All that was said with regard to them was that they represented Palmer as beaten in a contest, but for anything he knew to the contrary Palmer might have made such a gallant fight that, so far from bringing him into disrepute, the pictures might have quite the contrary result. He must refuse the injunction.

## Correspondence.

- \*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- \*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE TEST OF "PURE PHOTOGRAPHY."

To the Editors.

Gentlemen,—Unfortunately, I was not at the meeting of the R.P.S. when Mr. Bennett spoke about his impressions, as exemplified in his photographs; but I gather that there was some antagonism of ideas in reference to (1) a definition of impressionism, and (2) the possibility of control in the production of a genuine photograph.

"Impressionism" is a term very much bandied about in photographic conversation; but I submit, with much humbleness, that it is rather out of the way of the camera altogether. Judging by a protracted correspondence in another journal, it would seem to be accepted as a synonym for "fuzziness," which is the most ridiculous instance on record of the plagiarising by photographers of terms belonging to art. I can make good this assertion if I am asked to.

Regarding the other question, I am not on my own ground; therefore I come, cap in hand, to ask whether it is really a fact that photographs are considered by some to stand or fall by the test of their being capable of multiplication without variation. My dictionary gives no such definition of a photograph. From the collector's point of view, it must be a disadvantage for a picture to pass such a test, for it would rob it of as much individuality as belongs to a penny roll. Not that stereotyped repetition is beyond the power of the gum workers either. There is no end to human patience and skill. But why should a photograph be robbed of the added charm of being unique? There would be a distinction in an exhibited photograph which bore a label with this inscription: "No replicas—negative destroyed."

F. C. TILNEY.

### CHRISTMAS CARD TRADE.

To the Editors.

Gentlemen,—Many are the suggestions made to professional photographers, through the medium of your valuable journal, to increase their turnover, especially by the means of "side lines," and I am glad to record my own experience in this direction.

Some time ago you made the suggestion that use might be made of negatives by printing copies from them and present to our clients, tastefully mounted, in an appropriate Christmas card, intimating the superior merits of those over ordinary Christmas cards, and that copies could be obtained at a given price. I have adopted this means of keeping my name before my clients, finding my employees something to do in slack time, and, I hope, also bringing a little grist to the mill.

No doubt many photographers have adopted the idea to their advantage, but to those who have not I would say do so at once; it is not too late to secure a good percentage of orders before the purchases of private Christmas cards are made. My experience this season so far, has been that these complimentary cards have met with appreciation and secured a good percentage of orders. Beginning the first week in October, we have been steadily printing and sending out these cards, and in no case has this been allowed to interfere with ordinary business. Carefully selecting negatives, cabinet heads printed on C.D.V. pieces of paper, C.D.V. printed out of cabinet group, and so on, no subjects being reduced by copying, as this increases the expense.

In all about 150 cards were sent out, which I estimate to cost, including postage, 3d. per card. Up to the time of writing I have received orders to the value of £10 17s. 6d. Even as I write an order reaches me by post for a dozen cards at 7s. 6d. In addition to this, I have received many letters of thanks and appreciation, although containing no orders. I claim these cards have more than returned me their cost in the advertisement I get.

I thank you heartily for the suggestion I am pleased I adopted, and trust my experience will lead to others doing the same.—I am, dear Sirs, yours truly,

A COUNTRY PROFESSIONAL.

## ARC LIGHT IN THE STUDIO.

To the Editors.

Gentlemen,—Referring to my last letter, the lens used by me is No. 3 A Dallmeyer Portrait Lens, diaphragm No. 5, and Marion's S. plates, 250, H. and D.

The exposures vary from instantaneous to two seconds, in accordance with the light and shadow of my subject, but I consider that the rapidity of exposure is only secondary to the efficiency of the light for giving a range of effects.

As I only use retouching for removing freckles or little inequalities, it did not occur to me to send you unretouched prints. I now do so with the negatives, having had the varnish and retouching removed.

I think the time has now come when a non-competitive exhibition work done with artificial lighting would be most valuable and instructive.

There are a large number of photographers known to me throughout the country who, through the want of knowing the possibilities of artificial lighting, hesitate to embark, and there are many others who are prohibited from doing so, owing to the cost of the under-lying, and, I may add, many more who are unable to decide, through the confusion of the claims that are made for the various installations on the market.

I am confident if your paper would organise a small exhibition, limiting the number and size of prints from each exhibitor, all to be unretouched work, it could not fail to be interesting and instructive to a number of your subscribers.—Yours truly,

93, Linthorpe Road, Middlesbrough. R. E. FAIRCLOUGH.

November 17, 1906.

[Comparing the prints with those previously sent by Mr. Fairclough and with the negatives, we see that the retouching is very light, and in no way responsible for the lighting effect. Our correspondent's suggestion of an exhibition of artificial light portraiture one which we hope to act upon.—Eds. B.J.P.]

## MR. BENNETT'S PHOTOGRAPHS.

To the Editors.

Gentlemen,—It seems to me rather hard that a workman of Mr. Bennett's high standing should be described in your pages as being "known" "owing to his voluminous correspondence and lectures." I think that the Royal Photographic Society have placed on their walls a series of technical photographs that cannot fail to meet with their full share of appreciation by true lovers of photography. Doubtless the professional photographer, who relies on technical sound photography for his livelihood, as most do, will not fail to enjoy the treat; and I feel sure that if workers entered more seriously into the study of technical photography we should then have skilled workers worthy of their name, and the outcry against low wages could be a thing of the past.—Yours truly,

33, High Street, Bognor. L. R. GOODYER.

Of Mr. Bennett's technical photography we have the highest opinion. Our criticism of the photographs was put forward in reference to their claims to pictorial quality. We believe the notice the exhibition made this point perfectly clear.—Eds. B.J.P.]

**PHOTOGRAPHIC Sport.**—In all parts of the world, says "Country Life," the camera is largely supplanting the collector's gun, and of the two weapons the camera needs no less skill and patience, and often more courage in its use. Not a week passes in which this paper does not publish photographs which would have been incredible even a few years ago. The camera is revealing to us all the most secret corners of the wild things; and what it reveals it registers permanently, so that not the single student only, but anyone who will, is put in possession of the facts.

The South Essex Camera Club will have ready shortly a set of slides the work of members in Belgium, and a lecture by the President, Mr. Walter D. Welford, F.R.P.S. These will be loaned to other societies for a merely nominal booking fee, and as the dates will be arranged according to districts, the carriage one way will be much. Applications should be made to Mr. T. Michell, Hon. Sec., 180, Browning Road, Manor Park, E.

A POSTCARD dealer in Poplar, who was summoned for selling and retaining in his possession a number of improper cards, was fined £5 on consideration of the fact that he had informed the police from whom the cards were supplied wholesale.

## Answers to Correspondents.

\*\*\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\*\*\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*\*\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

\*\*\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

## PHOTOGRAPHS REGISTERED:—

D. Greco S. Smith's Place, Leith, N.B. Three Photographs of unveiling of the Leith Lurns Statue.

G. W. Davies, 49, Victoria Road, Ebbw Vale, Mon. Photograph of the Ebbw Vale 1st Rugby Team.

W. F. Austin, Burrowmoor Road, March, Cambs. Photograph of the Children, Staff, Education Committee and Local Managers attending opening of the new South District Schools, March.

J. Stuart, Thistlebank, Helensburgh. Photograph of G. MacLachlan, Helensburgh Town Clerk.

V. R. Windemer, Ewell House, Surbiton Hill, S.W. Photograph of the interior of St. Mark's Church, Surbiton.

**EMULSION FORMULA.**—Can you give a good formula for self-toning gelatino-chloride emulsion, also for gaslight emulsion suitable for postcards, and oblige.—X. L., Kent.

Such working formulae are trade secrets, and we know of none which we could recommend to you. The only information available is in patent specifications, particulars of which you will doubtless have seen in past issues of the JOURNAL and the "Almanac."

**COPYRIGHT INFRINGEMENT.**—Working recently as a process operator and outdoor photographer for a firm whose principal work was making half-tone blocks for postcards for a lithographic firm closely allied to us, I submitted about ten private photographs to the litho firm for their approval, the understanding being they would buy them if they were suitable, but no definite sum was stated. Some time after one was sent, among a number of their ordinary work, for reproduction, no previous notice having been given that they were using it. It was a half-plate print; the half-tone block made from it was 11 in. by 7. I wrote some time after inquiring about the others, and charging them for the one used half a guinea, but have received no reply. The photographs were not copyrighted. I should esteem it a great favour if you will give a little advice on this matter.—H. H. G.

As the photograph was not registered you cannot take action in respect of the infringement, but you can register now and stop further sales either by the firm or dealers in postcards.

**SILVER WEIGHTS.**—Could you inform me where I should be able to procure a set of apothecary's weights made in silver?—ALPHA.

We rather question if such weights are stocked by anyone. The most likely place to get them, we think, would be Oertling's, Turnmill Street, E.C. If they do not stock them they will make them to your order, no doubt.

**ENGRAVINGS.**—We wish to add to our business the sale of really good engravings. Can you tell us where to get these at wholesale prices? We refer to the fine engravings, artists' proofs, etc., sold by Messrs. Agnew and other firms of similar standing. We shall be much obliged if you can give us the information.—ENGRAVING.

The only source we can suggest is to obtain them from the publishers. Only a limited number of proofs are issued from

any plate, and these are often secured by subscribers and dealers before the prints are published. The fine impressions of old plates are usually purchased by the print-sellers at auction sales, such as those held by Sotheby's, Christie, Manson and Co., and others, or by private treaty with those who happen to have them for disposal. The firms of Goupil and Co., Franz Hanfstaengl, and the Berlin Photographic Company are publishers of high-class photogravures.

**TITTLING CARDS, ETC.**—1. Will you please tell me how to print the names on the bottom of postcards in gilt to look like gold letters? 2. Also, I have been trying to coat baryta paper with chloride emulsion; you will see by the enclosed it looks wavy. What is the cause of it? I draw the paper over the front of the emulsion in one-yard lengths very gently.—T. HARRIS.

1. The titles are printed on with one of the aluminium or Dutch metal printing inks—with rubber type most likely. 2. The wavy lines are due to the chilling of the surface of the emulsion by the cold paper. It is impossible, we believe, to prevent these unless the temperature of the emulsion is kept about 95deg. F. and only a very small portion of the paper is allowed to come into contact with the paper at once; which may be effected by drawing it underneath a roller so as just to touch the surface and carrying the paper straight up. For experimental work very satisfactory results can be obtained by floating the paper on the warm emulsion, but it would not be advisable to do this for larger sizes than about 12 by 10 or so.

S. E.—1. Probably to ripen a hypo-alum toning bath. 2. Dilution of the mountant will in no way affect the permanence of the photographs.

**PYRO SODA.**—Reading your comments on A. and C. formula, page 863, I observe you say C. formula (Bennett's) contains less carbonate and more sulphite than A. Is not this an error? As I read it, C. has  $1\frac{1}{2}$  grains more carbonate per ounce, and only  $\frac{3}{4}$  grains more sulphite. I think I can understand why B. is more active than A., but I will not forestall your solution.—W. P.

If "W. P." will again refer to page 863 he will find that B. is Mr. Bennett's formula, and that, as we stated, it contains less carbonate and more sulphite than A. We should be glad if Mr. Powney would give his explanation of the greater activity of B. over A. We do not in the least mind our solution being forestalled. On the contrary, we shall be glad of any hint likely to lessen the work of the investigation, which will probably take several months, and may lead to very little. This particular feature is only one of the minor problems, and there are several very probable solutions. If "W. P." can suggest another we shall be only too glad to test it.

H. H.—1 and 2. "The Photographer," 21 and 26, East 21st Street, New York. 3. In Africa. "The South African Photographer," Harp Alley, Farrington Street, E.C. Australia: "Australian Phot. Review" (Baker and Rouse, George Street, Sydney), and "Australian Phot. Journal" (Harrington and Co., George Street, Sydney). In India, St. Veronica, Merlin Park, Old Bally-Gunga, Calcutta.

J. J.—If you can tell us which firms have failed to give you satisfaction we may be able to advise you. In the absence of this information we obviously cannot.

W. DABY.—See answer to "Safelight," p. 900 of the B.J.P., for November 9.

**ALBUMINISED PAPER.**—I have received a packet of albuminised paper for the purpose of making photographs from my own negatives, to use for crystoleum work. I am just trying my hand at it. The maker's name is not on it, and there is no formula for toning and fixing, and photographers are not in the habit of using it, so they cannot help me much. If you can help me, I shall be much obliged for any hints. Is this paper permanent?—NOVICE.

The use of albuminised paper has declined of late years. Printing must be carried rather deeper than is required in the finished print, and the print then well washed till free from all soluble silver salts, which is known by the absence of milkiness in the water, and either of the following baths used:—

Sodium acetate .....	30 grs.
Chloride of gold .....	1 gr.
Boiling water .....	8 ozs.

Instead of acetate an equal weight of borax may be used. The baths may be used when cold and toning continued till the

desired depth is reached, which is to be judged by looking through the print. Fix in clean hypo bath 3oz. to the pint rendered alkaline with ammonia or soda, then well wash. The permanency of the prints depends upon so many factors that it is impossible to definitely say one way or the other; prints, however, are probably as permanent as any other silver printing-paper.

P. CARD.—The Rotary Photographic Co., Ltd., New Union Street, Moorfields, produce postcards of the kind you send on the largest scale.

PERPLEXED.—1. Nothing satisfactory except copying and printing from the new negative. 2. Houghtons, Limited. 3. ... covering power they are.

H. R. HILL.—Order "Trick Photography," ready in a day or two from Marshall Brooks and Chalkey, Harp Alley, London, E.C.

J. HOWE.—The stain is from the silver in the film of the postcard. You will find one formula for its removal on p. 956 of the "1960 Almanac," or page 965 of the 1907 "Almanac," read December 1.

H. P. AND CO.—We think you will not be able to copyright the matter. In any case, it is a form of words very generally used, and your proposed type-setting has not much to recommend it. We hope that in the event of your issuing the circular you will expunge the vulgarity, "photos."

**THIOCARBAMIDE TONING.**—You strongly recommended some time since the thiocarbamide toning bath in preference to the usual sulphocyanide. I have perseveringly tried it for over two months, sometimes satisfactorily, other times not, yet I always mix the bath the same, which is according to the formula given in the BRITISH JOURNAL Yearbook. It may be the water of the neighbourhood has something to do with it. Anyhow, I think I could better understand the matter if you would kindly give me the reason of adding the different ingredients, what acts the salt in the bath has, and the reason of the addition of acid. If I knew this perhaps I could modify the formula to suit my work. The last few weeks the bath has been terribly slow. Is this because the stock is two months old? (Unused stock, course.) Then the amount of salt you recommend the print to be put in before washing, viz., 2 oz. in 20 oz. water. Is this not excessive? and would it rob some papers of the power to tone afterwards?—H. BRADSHAW.

The purpose of the thiocarbamide is to form a colourless salt (CSN<sub>2</sub>H<sub>4</sub>)<sub>2</sub> Au Cl which is soluble in excess of the thiocarbamide, and in which the gold is replaced during toning by silver. The acid prevents the chance of decomposition of silver thiocarbamide compound by an alkali, and it is quite possible that very hard water would suffice to cause this decomposition. The salt is to slow down the action of the toning bath, and also to convert any soluble silver salt into chloride. The preliminary salt bath, if removed by washing, would rob the solution of its toning power. The slow toning is due to the stock solution being old, for although when mixed bath keeps well, there must always be some change going on and this tends to the formation of a more stable salt of gold. Our experience is that the bath acts too quickly, but then we always keep stock solutions of the chemicals and mix as wanted.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The "British Journal Almanac" is this day published simultaneously in all parts of the United Kingdom. A synopsis of the contents is given on page 952.

A correspondent gives some practical advice on how to resist the attacks of the "free-enlargement" canvassers. (P. 958.)

Colour Photography.—A new three-colour printing process has been worked out by Dr. Traube, in which the dyes are precipitated (silver iodide). (P. 944.)

A new work on the Lippmann process of colour photography is reviewed by Mr. E. J. Wall on page 946.

M. Estanave, a colleague of Professor Lippmann, has described a variation of the parallax method for stereoscopic projection. (P. 945.)

Messrs. Elliott and Sons, Ltd., have obtained from the Postmaster-General the statement that postcards of less than the present statutory size will be allowed to pass through the post until April, 1907. (P. 958.)

Mr. Douglas Carnegie contributes an article on the chemistry of the sulphide toning process in which he raises several points of importance to those using the process in ordinary work. (P. 947.)

Impressionism in art and its relation to photography is a topic which has arisen from the recent address by Mr. H. W. Bennett. Photography, impressionism must be largely a matter of "fake." (P. 944.)

Mr. George Bernard Shaw last week expressed his views on the deplorable condition of the artistic professions under "ideal" social conditions. (P. 953.)

The conclusion of the Traill-Taylor lecture by E. Walter Maunder "Photography in the Work of Greenwich Observatory" is given on page 949.

## EX CATHEDRA.

### The 1907 Almanac.

To-day the issue of the "British Journal Almanac for 1907" is obtainable throughout the United Kingdom, and many of our readers, we doubt not, will hasten to possess themselves of the latest, and, we may add, the largest "Almanac" issued since the establishment of this publication in the year 1859. Congratulations are due to our publishers on issuing 25,000 copies, each of 1,624 pages, one day in advance of the advertised time. That they have done so is in part a result of the thoughtful co-operation of advertisers, who have realised the herculean labours which the publication of such a volume entails, and have been early in giving their orders or supplying the insets that are a feature of the "Almanac." Our publishers desire us to express their grateful acknowledgments of this consideration, and, at the same time, their regrets that announcements intended for the "Almanac," have had to be omitted owing to the impossibility of dealing with orders received after the scheduled date.

\* \* \*

### Processes in the "Almanac."

The text pages of the "Almanac" are as varied as ever, and in one or two minor respects it has been found possible to improve on the arrangement of the contents introduced last year. In another column we give a brief conspectus of the information compiled and classified from all sources. The section "Epitome of Progress," which was made a feature of the 1906 volume is very materially strengthened, but not in the direction of purely chemical and photo-chemical researches, for the results of which we can quote no better referendum than Dr. Eder's invaluable "Jahrbuch." The more practical aspects of photography have been our immediate care in supervising the abstracts which are collected each in its proper place in the "Epitome" section, and we would flatter ourselves that the photographer does not exist to whom the pages of this section of the "Almanac" alone cannot prove informative.

\* \* \*

### The Misuse of Affiliation Sections.

A correspondent in a contemporary attributes a falling-off in the attendance at his society, and a growing apathy on the part of the members, to the too free adoption of lectures supplied by what he calls a "society of societies," which we may assume to be an organisation on the lines of an affiliation. He complains that their season's programme is now almost entirely made up of borrowed "affiliation" lectures, and of trade demonstrations, and seems inclined to place the majority, if not all, the blame for this state of affairs on the existence of such things as affiliations. It seems to us, however, that he is putting

the blame on the wrong shoulders. Affiliation lectures are not forced on the societies, who need not use them at all. If any society suffers from a surfeit of them it is entirely its own fault, and the proper remedy is the changing of the officials responsible for the programme. If a secretary cannot find among the members of his society more than one or two members capable of giving a lecture, he ought to be able to find several who can demonstrate a process, and a few more capable of arguing with the demonstrators. If he cannot do this, it appears to us that only two conclusions are possible: either he is a bad secretary, or his society is an altogether superfluous one, with no excuse for existence. In every society that has reason for its existence there are means of keeping the members interested, and of drawing out those capable of interesting others, quite apart from outside help and strange demonstrators. A good secretary will find ways and means of keeping his society alive, but he will not attempt to do it by filling the programme with affiliation lectures and trade demonstrators. In most societies there are far too few informal meetings of the members, devoted to chatty and quite casual discussions, with comparisons of apparatus, etc. If such meetings are interspersed between the "ordinary" meetings, a sociable secretary will soon find that many members, who as a rule have nothing to say in the ordinary meetings, can bring out many interesting subjects over a pipe. A little persuasion and encouragement will induce many of them to elaborate their special subjects and pave the way for more formal demonstrations. Without such informal meetings it is difficult, if not impossible, for the secretary to become as well acquainted with the members and their capabilities as he should be, and until he is well acquainted with the majority of them it is impossible for him to determine what latent talent there is in the society.

\* \* \*

#### A New Three-Colour Process.

Elsewhere will be found the first notice of a new method of three-colour printing, which has been worked out by Dr. Traube, of Berlin, who was for some time associated with Dr. Miethe in his colour work. Brief as are the details yet to hand, it is obvious that the process is an extremely ingenious one, and it may be summed up by stating that positives are made from the three constituent negatives, the silver images converted into silver iodide by the solutions containing the respective dyes; the silver halide is then dissolved out, the dyes fixed and the pictures superimposed. The principles involved naturally strike one as precisely similar to those employed in ordinary dyeing or the preparation of pigments from aniline colours. It is a well known fact, for instance, that many insoluble salts which when added to a solution of a dye are quite inert will, in *statu nascendi*, carry the whole of the dye down as a precipitate leaving the supernatant fluid quite colourless. If we assume, then, that the silver iodide at the moment of formation retains some dye, it is easy to understand how subsequent treatment with tannin, or a metallic salt, may form a lake or actually dye the gelatine *in situ*. This view is borne out by the fact that for basic dyes tannin is used, and it has been proved by Juste Koechlin that tannin will form soluble or insoluble lakes according to the proportion of the tannin and colouring matter used. The supposition, too, that the gelatine is actually dyed is warranted by the fact that many dyes will not take on certain fibres, unless the latter are "animalised" or treated with gelatine or albumen. In the case of some dyes, too, treatment with tannin is essential to confer on them fastness to light. The acid dyes, on the other hand, like all

acids, contain hydrogen atoms which are readily replaceable by metals and form insoluble compounds, particularly with metallic hydrates.

\* \* \*

#### Some Possibilities.

The principle of Dr. Traube's process, of course, may, in other ways, be applied in other ways, because silver iodide is not the only salt which has the power of tenaciously holding dyes; as is known from old researches in orthochromatising in which the chloride and bromide of silver are used. Nor does it seem actually necessary for the halide to be in the nascent state, a lantern-slide converted into bromide can be soaked subsequently in a dye solution, be deeply stained, and the bromide removed, leaving the dye distributed throughout the gelatine yet showing an image. By subsequent treatment the dye may be discharged from the gelatine, distinct from the image and a transparency appears composed solely of dye left behind. This particular method was adopted with crystal violet. An ordinary lantern-slide was treated with bromine water, thoroughly washed, soaked in crystal violet solution, then treated with hyposulphite and well washed. The appearance then was a violet plate in which, however, the image was distinctly seen. In order to ensure complete absence of silver, a strong mixture of hyposulphite and ferricyanide was applied to the plate well washed. To discharge the dye a bath of weak hydrochloric acid was used, which, changing the colour to green, freely dissolved it, and subsequent washing with ordinary and very hard tap water at once produced clear whites and a violet image, which apparently consisted only of dye. As many double ferricyanides also possess a very strong affinity for basic aniline dyes there is no reason why silver ferricyanide should not act in precisely the same way. The obvious difficulty, however, lies in preventing the gelatine where there is no image from becoming coloured, or in knowing how to discharge the colour from it.

\* \* \*

#### Condensed Moisture and Ruined Negatives.

The excessive humid atmosphere we have had during the past few weeks has been a prolific source of stained and ruined negatives. Few amateurs, and even some professionals, take the trouble to varnish their negatives, the result that they frequently become badly stained with silver during the printing. These stains, more often than not, are attributed to damp paper, whereas they are really due to damp negatives. Gelatine is a great absorber of moisture, and if unvarnished negatives are left long exposed to such a damp atmosphere as we have had lately the film will absorb a good deal of it, with the result that when quite dry paper that contains free nitrate of silver is printed on them the negatives become stained. The stains may not make their appearance at once, but they may do so at a future time, perhaps weeks or months afterwards. During the winter months printing is usually carried on out of doors. There the negatives and frames often become exceedingly cold, when they are taken into a warm room to change the paper moisture at once condenses on them. This can be plainly seen on the glass side of the negative, but is not noticeable on the film side, though it is there all the same, the gelatine, if unvarnished, absorbs much of it. Consequently, when many prints are made, with these conditions prevailing, the negatives become stained with silver. Usually when a negative becomes silver stained it is put down to contact with damp paper, while in fact the time the cause is dampness in the film. P.C. as sent out from the makers is always perfect.

dry, and it must be very carelessly handled by the user if it becomes sufficiently damp to cause trouble. The remedy for, or rather the preventative of, silver-stained negatives is to varnish them. The cost of the varnish is a mere trifle, and the trouble of its application is next to *nil*.

\* \* \*

#### Groups by Flashlight.

A class of photograph which is now becoming very common—a decade or two ago it would have been looked upon as impossible—is that of theatrical scenes, groups in rooms, dinner parties, and the like, taken by artificial light. Some of these photographs are very satisfactory, while others are just the reverse. Those which are taken by photographers who make a specialty of this class of work, as a rule, are good, or at least as good as circumstances will permit; while those produced by others, whose experience is limited to perhaps their first attempt in this direction are very far from being satisfactory. A very frequent question that is put to us is something to this effect:—“I have been asked to photograph a dinner party, with the guests seated at the tables. What lens should I use, what flashlight should I employ, where should the light be placed, and how much powder should be used, etc.?” Now, these queries are really impossible to answer in anything like a satisfactory way without seeing the building or knowing anything of the conditions under which the photograph has to be taken. With regard to the lens, one of the rapid rectilinear type, or an anastigmat, is generally the most useful, by reason of its rapidity, but it goes without saying that its focus should be such as will include all the subject desired on the plate, otherwise a wider angle one must be employed, which usually means a smaller aperture. As regards the light, magnesium powder, used in one or other of the flash-lamps, is decidedly the safest in inexperienced hands to employ, but the flashlight, being more sudden, there is less chance of movement during the brief exposure. Whether more than one light should be employed, of course, must depend upon circumstances—the size of the room, or the area to be illuminated—but where more than one light is used all must be fired simultaneously, and in all cases the subsidiary lights should be less brilliant than the primary one—they should only be used to soften the shadows. As the Christmas season is now approaching, and possibly some photographers who are not *au fait* with this kind of work may be called upon to record the events, a few practical hints may be useful to them just now. One is that the camera and lenses be taken to the place the day before, or earlier in the day, the picture is to be taken, and the lenses tested to see which best covers the plate and includes all the subject desired. A test should then be made to find which stop is required to get all portions, near and distant, in tolerably good focus. This cannot well be done when the party is assembled. Next a couple or three trial exposures should be made in the empty room with different quantities of magnesium or flash powder differently placed. If these preliminary trials are made there should be no chance of failure in obtaining a satisfactory result. This may seem a troublesome procedure, but it is advisable, seeing that the photographer's credit may, to an extent, be at stake, and that the event is not likely ever to be repeated in its entirety. It should be kept in mind that in the case of a dinner party the white cloths on the table reflect light, and thus tend to soften or even destroy the shadows, and this should be taken into account when more than one source of light is employed. It goes without saying that rapid plates should be used, and that they should be backed so as to avoid halation, which would otherwise infallibly mar the work.

#### Foreign Letters and Metric Weights.

Everyone knows that the postage on letters for abroad is 2½d. per ½ oz., and it will be remembered that some months back it was given out that a letter to France or Germany bearing a 2½d. stamp would be delivered without surcharge, even though it weighed more than ½ oz., provided its weight did not exceed 15 grammes. We were reminded of this a few days ago by seeing in a stationer's shop window in the City a set of letter weights—15, 30, and 60 grammes. The price of them was 1s. 6d. Now, the difference between ½ oz. is but, roughly, 13 grains, still, little as it is, it may on occasion mean all the difference between 2½d. and 5d. on a letter to either France or Germany.

\* \* \*

#### Storing Cameras for the Winter.

Now that winter is obtaining a firm footing, many workers will not require to use their cameras again for some months; not that there is no outdoor work to be done in winter, but simply that they do not care to do it, or for other reasons. At any rate, there are hundreds of cameras that will lie idle during the months of winter. In too many instances they are simply put away, just as they were last used, in the lumber room, frequently an attic none too dry—we have even known them to be kept on a shelf in the darkroom—with the result that when next required to be used they are found to be in anything but good working order, and a considerable amount of time and trouble has to be expended on them. All this might have been avoided had a few minutes been bestowed upon them before they were put away. If the apparatus should have been much used out of doors during the recent damp and humid weather, the woodwork and the lining of the bellows will have absorbed a considerable amount of moisture, and, unless this be got rid of there will be the risk of the former swelling and the latter becoming mildewed, during the long storage. Therefore the slides, with the shutters drawn, and the camera with the bellows extended, should be left exposed in a warm and dry room for a day or so, for the absorbed moisture to escape. The slides and the camera, in all its parts, should be carefully dusted, and if the bellows of the latter has been noticed, during the summer months, to stick together in the gussets they should be liberally rubbed over with French chalk, which will prevent their sticking when packed away. After these precautions have been taken the camera and slides may be put into the case, and the latter parcelled in one or two thicknesses of brown paper and stored away in a dry place. The lenses, after dusting, should be wrapped in tissue paper and kept in a drawer. If these few precautions are taken, the apparatus will be found ready for immediate use, without further trouble, whenever required. If they are neglected, it may happen that much time and trouble has to be spent to get it again in good working order. This may sometimes mean that it cannot be used at all if it were required in a case of emergency.

PHOTOGRAPHIC Goods for Italy.—According to a consular report, in the import of cameras, lenses, photographic plates, films, etc., there is keen competition with America and Germany, but principally with the latter, on account of their cheaper prices and the facilities they give as to credit, which is an inducement to the dealers to recommend German-made articles. British-made articles are, however, in great demand on the part of tourists, and a good trade is carried on. British camera-manufacturers should endeavour to meet the wishes of local importers, as far as may be possible, and send out travellers with cheap patterns; each apparatus should be accompanied by instructions in Italian.

## IMPRESSIONISM IN ART AND PHOTOGRAPHY.

MR. H. W. BENNETT's address at the R.P.S., and the discussion that followed (reported on page 916 of our issue of November 16), showed the confused ideas that seem to exist among photographers with regard to the meaning of the word "impressionism." The fundamental mistake seems to be in assuming that it can properly be applied to more than one description of art. It is not our intention to review the phases of art into which impressionism has entered, though such an exercise would show us the fallacy of the general view that impressionism is a clever disguise for slovenly technique. Really, the great impressionists like Manet, Degas, Corot, and Monet, are masters of their art, not to be classed with tricksters who manage to cover their want of skill by affectations.

The term "impressionism" has really a narrow meaning, in spite of its wide application. It should only apply to pictures which record the impression of light and air that a scene makes upon an artist who wishes to see, in that scene, *nothing else so forcibly*. Such impressions are naturally the very opposite of topographical records, and are also incompatible with the landscape compositions aiming at familiar pictorial beauties. They are really "studies" rather than "pictures." Perfect realisation of light and air may exist in the ordinary picture, nevertheless, as it does, for instance, in the works of Claude, Turner, and others; but the preparatory studies for such effects must, of necessity, be pure trials done at a white heat, in the shortest space of time. In them drawing and detail can find but short shrift. The French painters following Manet, who practised this method of seizing certain essentials to obtain truth of effect in their studies, were content to leave their work at that stage rather than incorporate its results in large and ambitious works such as Turner produced. These studies were then called, by those who were not educated to them, "impressionistic pictures."

The question now arises how can impressionism be represented in photography? If the photographer wishes to show a subjective impression he must fake. He must depend on brush or pencil, and if he can fake with these perfectly he is obviously very foolish to handicap himself with a camera at all. Fugitive aspects of Nature are very difficult to photograph, and the emphasis that the painter can give them is impossible to the photographer without faking.

Disturbing details must be suppressed, otherwise the fugitive effect aimed at is probably not to be distinguished on the negative. The photographer may be helped by natural mist, as pointed out by Mr. Bennett, but he will not once in a lifetime find the mist to be just where he wants it, and in the right quantity. He probably will not know this, for he lacks the twenty years or so continuous observation and study of Nature that is necessary to make the mature painter. For the same reason he cannot fake his result with sufficient ability to produce a passable result. At his very best his ignorance is displayed where he least expects it, and if he only knew enough to avoid this betrayal he would know too much to attempt impressionism with a camera.

The photographer has a field of his own where the painter cannot touch him, much as he would like to. But true impressionism is the special preserve of the painter and the writer. The camera has no chance there, and its owner acquires the necessary knowledge and skill to qualify himself for impressionistic work the camera is the very last tool that he will dream of using.

In the R.P.S. discussion Mr. Lambert touched on one essential truth when he dwelt on the need of knowledge, and Mr. Thomas rounded off this argument by suggesting that a sheet of paper and a piece of charcoal gave better opportunities than the camera. Given the training and knowledge, this would be undoubtedly the case with impressionistic work, and the idea of a thoroughly trained man attempting such a work with a camera is beyond our comprehension.

It has very truly been said that we are naturally nearly blind to colour, and quite blind to form. These defects are overcome by training alone, and it is far more difficult to overcome them than it is to master the simple manipulation of brush or pencil. It is even more difficult to master what we may call the scientific principles of picture-making as the great impressionists mastered them, and even a moderate degree of ability is only attained as the result of many years' continual study. We may well ask where this close study is represented in the training of the photographer. How can he hope to do without it, and how can he attain it with nothing but the camera as a training master? It must surely be obvious that the highest branches of pictorial art, such as true impressionism, are closed absolutely to the photographer, and that his proper and only safe course is to devote his energies to such branches of graphic work as the camera is especially adapted for.

## A NEW THREE - COLOUR PRINTING PROCESS.

DR. TRAUBE, of Berlin, recently exhibited at a meeting of the Photographisches Verein in Berlin, examples of a new process, not only for obtaining transparencies in colours, but for making three-colour prints.

The process is based on the fact that silver iodide can be very deeply stained with aniline dyes, and that it retains these dyes very tenaciously. It has been known for a long time, of course, that the chloride and bromide of silver could be stained and rendered colour-sensitive, but Schaum stated that it was not possible to stain iodide because of its crystalline character. Lüppe-Cramer on the other hand, proved that it could be stained, but that even then, although in an amorphous condition, it was not colour-sensitized.

Dr. Traube has discovered that so far as his experiments have gone, there is no basic dye which is not taken up by silver

iodide, and that many of them adhere so tenaciously to it that they can neither be removed by washing nor by the action of oxidising or reducing agents. Of the acid dyes, those belonging to the eosine class are the only ones which stain the iodide deeply, and this may of course be due to the introduction of the halide molecule as in all cases this produces greater insolubility. The application of a solvent of silver iodide to the stained film naturally dissolves it out, and leaves the dye diffused throughout the gelatine in such a condition that it can be washed out.

These facts are the basis of the new process. Some lantern slides were shown, which, judging from the report of the meeting, left nothing to be desired as regards modelling and they contained the dyed iodide as an image. The action of light on silver iodide is so little and so slow that it is stated that

may be considered as practically permanent; should, however, a colour be bleached somewhat, it can be again stained up by immersion in the corresponding dye bath.

The paper prints exhibited by Dr. Traube had all the appearance of carbon prints, and were prepared by the superposition of three stripped films, which were made in the following manner. Ordinary transparencies were made on celluloid films exposing through the support, thus doing away with the necessity of double transfer. These transparencies were then converted into dyed images by immersion in solutions which converted the silver into iodide and simultaneously dyed them respectively red, yellow, and blue. The iodide was then

dissolved by fixation with special solutions which in the case of the basic dyes contained tannin, and in the case of acid dyes certain metallic salts, the dyes thus being converted into colour lakes. Nothing was now demanded but to strip and superimpose the images, which is done without the use of any supplementary solution. The results are described as extremely satisfactory, showing the finest details and the most delicate half tones.

Doubtless we shall have somewhat fuller descriptions to hand within a short time, and as it is stated that the necessary materials are to be placed on the German market, the dyeing solutions being called "Diachrome solutions."

## STEREOSCOPIC PROJECTION BY MEANS OF RULED SCREENS.

(A Paper read before the Paris Academy of Sciences.)

There are two essentials for the production of relief are:

- (1) To observe binocularly two prints representing two perspective drawings of the same object;
- (2) To observe these prints in such a way that the image intended for the right eye is seen by that eye alone, and that for the left eye by the left alone.

If these conditions are observed, the effect of relief is obtained. In these lines I have devised a projection screen onto which a pair of stereoscopic images are projected, at such convergence that homologous points in the distance of the view, e.g., the horizon line, coincide. The images of nearer points do not fall on each other, but are separated by a horizontal distance, the "stereoscopic parallax," so called by Helmholtz. The separation is greater, the nearer the objects to the observer and the camera.

When these partly superimposed images are seen, by transmitted light, on the screen, each eye perceives one, to the exclusion of the other, and the sensation of relief is experienced. The action of the screen makes it possible to dispense with any instrument for the eye of the observer, and the stereoscopic effect is very readily seen.

The theory of the process is as follows:—

Let M (Fig. 1) be any point in an object, O and O<sup>1</sup> two sources of light, and EE<sup>1</sup> a screen, in front of which is a ruled grating, RR<sup>1</sup>. The light O casts a shadow m of this point on the screen, and, and the light O<sup>1</sup> a shadow m<sup>1</sup>. If it were possible to mark on the screen the shadows m and m<sup>1</sup>, and to place the two eyes in the positions, O and O<sup>1</sup> (the object M being supposed eliminated), each shadow would be seen by each eye, to the exclusion of the other. For a suitable position of the grating the eye at O<sup>1</sup> will see a shadow m<sup>1</sup>, but not m, as the visual ray from m<sup>1</sup> to O is intercepted by an opaque bar of the grating. Similarly, m<sup>1</sup> is seen from O, but not from O<sup>1</sup>. Thus, if the observer receives these two separate impressions, he will obtain the sensation of stereoscopic relief as if he directly regarded the object having cast the shadows.

The screen thus serves to cut off from each eye the shadow which it should not see.

But all the points of the object will not give two images such as m and m<sup>1</sup>. For example, the point M would give only the image m<sup>1</sup> by the light O<sup>1</sup>. That from O would be cut out by a bar of the grating. The images formed by each source of light on the screen will thus be incomplete, and will be as if formed by cross hatching. But, as we have seen, that will have no influence on the observation of the images, owing to our tendency to combine, in the impression formed by the brain, any discontinuity in the images, so long as the latter falls within certain limits. This tendency

explains the sensation of continuity which we get from the cross-ruled half-tone engravings, in which we fail to recognise the square-formation.

The distances of the lights O and O<sup>1</sup> should be equal to the inter-ocular separation, since in an observation the eyes take the place of these lights. The distance varies with different observers from about 5.5 cm. to 6.4 cm. The ruled grating should be placed at such a distance from the screen that the rays of light from O meet the screen in the portions where the light O<sup>1</sup> projects the shadows of the opaque bars of the grating, and *vice versa*. These conditions are realised if the luminous rays from O and O<sup>1</sup>, and the tangents to two consecutive edges of the two bars of the grating meet on the screen. Then by similar triangles, OIO<sup>1</sup> and αIα<sup>1</sup> (Fig. 2),

$$\frac{z}{D} = \frac{l}{2a}$$

z denoting the distance of the grating from the screen, D that of the lights from the screen, l the separation of the two opaque bars of the grating, and 2a the separation of the sources of light.

On the lines of this formula I project, on to the same part of the screen, the two stereoscopic images of an object in super-imposition. In the experiments made in the laboratory of M. Lippmann, at the Sorbonne, I attained this result by placing two prismatic objectives in front of the stereoscopic pair. By means of a lateral displacement of these two lenses the two images were brought into stereoscopic, i.e., partial, coincidence, the effect on a ground-glass screen being total confusion. On receiving the double image on a screen carrying a ruled grating, of ruling, etc., to satisfy the conditions stated above, the observer, on fixing his gaze in the determined direction, sees the subject projected in relief. The special screen is formed of two ruled parallel line gratings,

Fig. 1.

Fig. 2.

separated by a transparent screen, such as a ground glass. The distance of the gratings from the glass is adjusted to the fineness of their ruling. One of these gratings plays the part of the grating RR<sup>1</sup> (Fig. 1) in order to coalesce the two

projected stereoscopic images; the other serves to separate the two images thus combined.

There is a fair amount of licence as to the observance of the enlarged images, and several persons conveniently placed can see them at one time, the number increasing with the size of the projection. Up to the present I have worked with screens of various sizes up to 20 by 25 cm.

If, in place of the special screen (but all the other observations remaining the same), we place a photographic plate, with the ruled grating in front of it, at a suitable distance, a negative stereoscopic transparency is obtained, a positive from which, when observed through a ruled grating of the same character, exhibits a distinct relief. This is a process of obtain-

ing relief effects from stereoscopic negatives which has certain advantage. Enlarged stereograms can be made in this way.

Lastly, one direct result of the employment of the special screen is the projection of small objects in relief. For this purpose, in place of stereoscopic images, as described above, the two images of the strongly lighted object are projected on to the screen, say by means of one large lens provided with two diaphragms at the inter-ocular separation. We thus obtain two stereoscopic images of the object which, when observed through the screen, reproduce the object in relief.

In the conditions which I have described in this paper, real images are observed as distinguished from the virtual images usually obtained in stereoscopes.

E. ESTANAVE.

## A TREATISE ON LIPPMANN COLOUR PHOTOGRAPHY.

A NEW work on Lippmann's process, particularly if, as foreshadowed in the technical press, it contains distinctly novel and improved methods of working, is always worth attention. Dr. Hans Lehmann, of Jena, is the author of a new work that has just been published, and which has already been mentioned in these pages.<sup>1</sup>

Naturally, it opens with an historical sketch, and it is regrettable that this is not a little more accurate. Valenta, for instance, is accredited with being the first to use a gelatine emulsion, and this is all the more curious in that, although Dr. Lehmann gives references to Valenta's work, the latter himself gives<sup>2</sup> priority in this respect to MM. Lumière, who, by the bye, might be non-existent or have done nothing, for they are not mentioned at all by Dr. Lehmann.

Fig. 1.

The further statement, that no one except Lippmann has made successful results of compound colours, is not correct.

Turning, however, to the author's actual work and improved methods, we find him first dealing with mixed spectral colours, and for this he uses a total reflecting prism in front of the camera lens, which receives half the beam of light, and, by revolving this, is able to bring any pair of wave lengths into coincidence. This is distinctly new, so far as I can find, and useful, because it avoids any displacement of the rest of the apparatus, and the exposures can be simultaneous.

The chief novelty in Dr. Lehmann's work, however, appears to be improvements in sensitising, and the use of a special

Fig. 3.

filter. He states that hitherto the method such as used by Valenta and Neuhauss consists of an accurate adjustment of the quantities of dyes, so that the plate without a filter will give pure whites. This method the author abandons, and adds

(1) Beiträge zur Theorie und Praxis der direkten Farben Photographie mittelst stehender Wellen nach Lippmanns Verfahren. Published by C. Troemners, Freiburg. "B. J." Oct. 26, p. 346.

(2) Die Photographie in natürlichen Farben. By E. Valenta, Knapp, Halle, 1894, p. 47.

enough dyes to give distinct maxima of action, whilst correct adjustment is obtained by the use of the filter.<sup>3</sup>

The former method Lehmann calls the "photo-chemical adjustment," and the latter "physical adjustment."

Turning to the practical section of the work in the hopes of finding new sensitising formulæ, we are met with the statement that the plates prepared from the author's formulæ are to be obtained commercially from Kranseder and Co., of Munich, as is also the filter, the use of which, by the bye, is patented in Germany.

Apparently Dr. Lehmann has overlooked the later work<sup>4</sup> of

Fig. 2.

Neuhauss, as his footnote as to the sensitising merely refers to Neuhauss's book published in 1898; the latter has tested Dr. Lehmann's plates, and states<sup>5</sup> that they possess no better red sensitiveness than any others. Considering that plates prepared according to Neuhauss's last formula give a closed band in the spectrograph from C to N in the ultra-violet, one would hardly want more.

The suggested filter, a mixture of cyanine, erythrosine, and æsculine, must cut down the orange and green besides the ultra-violet; the exclusion of this last is not new, of course. The action of this filter in the reproduction of white is

(3) The composition of this filter is given in the "Journal" for Oct. 26, p. 346.

(4) Eder's Jahrbuch, 1901, pp. 115-126.

(5) Photographische Rundschau, 1906, p. 154.

graphically shown by the author in Fig. 1. The shape of this curve will at once recall to every colour worker's mind the familiar figure of the absorption curves in three-colour work. Unfortunately, from the practical point of view, this filter is only for daylight work, and a fresh filter has to be "physically adjusted" for each illuminant, and as it is possible, as proved by Neuhauss's work, to use his plates with no filter at all, or only a pale yellow to reduce the preponderance of blue, this new proposition does not strike one as a great advance. There are many other little points on which one might question the author's conclusions, particularly with regard to the use of a sheet of ground glass, instead of the familiar prism, to destroy the surface reflection. Slow as the Lippmann emulsion is, too, one must doubt the wisdom of omitting altogether any fixing bath, nor can one accept without demur that the grain in the emulsion, which can be seen, without exposure and development, with an eyepiece, is due to structure in the gelatine. That gelatine is not a homogeneous substance has been proved by Zsigmondy and Neuhauss<sup>6</sup>, but they used the ultramicroscopic method, not a simple magnifier.

A statement which is open to question is the effect of crossed spectra, for, according to the author, increased reflection is caused by light of similar wave length, whereas Pfaundler and Neuhauss<sup>7</sup> say that black stripes are formed by interference.

The author is to be warmly congratulated on the photomicrographs of some of his spectra films, the sections being cut by Dr. Böhm, of Munich, and photographed by Dr. Köhler, of Jena. But even here there is a fly in the ointment, because the sections were swollen in a mixture of albumen and glycerine to four or five times their original thickness, and therefore the distance between the laminae was increased to this extent, rendering the photographing of the same much easier than was the case when Neuhauss photographed his albumen section.

One of these sections is reproduced in Fig. 2, and represents well the laminar deposition of the silver, which was caused by the synchronous compound colour formed by the admixture of  $\lambda$  563 and  $\lambda$  482, the former being a yellowish green about D<sub>2</sub>E and the latter very close on the violet side of F. The distance between the laminae being enlarged 10,300 times.

The extremely dense left-hand side of this preparation was that next the mercury mirror, and by careful examination it will be seen that there are seven recurrent laminae or maxima,

five being very distinct and two much weaker. This periodic maximum and minimum recurrence is explained by Dr. Lehmann by the following diagram, Fig. 3, which represents two rays of above wave-length proceeding along the same path, and it is obvious that the more the crests of the waves coincide, as at the left-hand of the figure, the greater must be their action, whereas on the right, where the crests do not coincide, there is less action, which may be represented by the top of the curve. The occurrence of these maxima in a vibration period may be calculated from the formula  $\lambda_2 \div (\lambda_2 - \lambda_1)$ , in which  $\lambda_1$  is the smaller and  $\lambda_2$  the greater wave length, the result being a number in which the fraction may be disregarded, or read as the nearest whole number, according as the fraction is greater or less than 0.5. Taking the above two wave-lengths, the actual number is, of course, 6.95, etc., which is read as 7.

The only point in this explanation which strikes one is that the upper curve, which is obviously intended to be the sum of the two lower ones, is not correct—that is, provided one accepts the explanation given by almost every other authority on interferential photography—nor is it correct even from this diagram itself. The usual accepted explanation is that where the rays cross, there being a pull on the ether particles in contrary directions, there is no light, and this is shown even in Dr. Lehmann's diagram in the upper curve at the end of the maxima, yet we have immediately following this, on the extreme right of the diagram, three wave crests with two crossing points, yet the upper curve shows maxima at these points, where theoretically there can be no light.

The book is extremely interesting, and the methods of examining the colours reflected by a Lippmann photograph with a spectroscope by isolation with a movable slit distinctly good. But whether everyone will accept the author's dictum that three-colour work is troublesome and costly is an open question, and many other debatable points are raised in the four pages which he devotes to the advantages of the process, probably one of the most debatable being that Lippmann's process is a means of artistic expression, an "ars pingendi." I cannot personally imagine a heliochrome being accepted, for instance, by the Linked Ring; but the proof of the pudding is in the eating, and the author's footnote to the above statement, that his results may be obtained commercially from Kriess, of Hamburg, will enable anyone, if the like, to test or taste the pudding.

E. J. WALL.

## THE CHEMISTRY OF THE SULPHIDE TONING PROCESS.

So far as I can ascertain, the chemistry and *modus* of the now popular process of sulphide toning of bromide prints has received but scant attention.

During the past summer I have been working on this process, and as it will be some time before I can command the leisure to continue my work, I thought it would be well to put on record the progress so far made.

### The Bleaching of the Print.

As a bleaching agent I have used in my experiments a solution made by dissolving 9 grammes each of ammonium bromide and potassium ferricyanide in 250 ccs. of water. This is practically the recipe given in the "B.J. Almanac." To save words, I shall henceforth refer to this solution as "the bleach."

A bromide print immersed in this solution is bleached almost instantaneously. As is well known, a print will bleach in a solution of potassium ferricyanide alone, but the bleaching takes place so slowly that an immersion for several hours is necessary for its

completion, and, it may be added, the tones obtained by sulphur-etting prints thus bleached are, so far as my own tastes in matter of tone are concerned, quite impossible. As Eder showed some years ago, the reaction which takes place when metallic silver is brought into contact with potassium ferricyanide solution may be expressed by the equation—

How is the extreme slowness with which a print bleaches in pure ferricyanide solution to be accounted for? May not the following observation furnish the clue to the answer? When potassium ferrocyanide solution is added to an excess of silver nitrate solution the precipitated silver ferrocyanide is flocculent, settles rapidly, and is easily washed in a filter or by decantation. But if the silver salt is not in excess the silver ferrocyanide is precipitated in a sticky, slimy form, which, on account of its coherence and impenetrability, it is next to impossible to wash in a filter even when using an efficient filter pump. Now in the bleaching of bromide prints we have silver ferrocyanide formed in the absence of any soluble silver at all, and presumably under these conditions the silver ferrocyanide takes the form of the slimy impenetrable modification just described. The formation on the surface of the silver image of a

(\*) Eder's Jahrbuch, 1906, p. 13.  
(\*) "B.J.," Oct. 12, 1906, p. 806.

thin coating of this almost impervious variety of silver ferrocyanide would clearly prevent the rapid conversion of the underlying body of the silver image.

### Why is Bromide an Accelerator?

The question now presents itself why the addition of ammonium bromide to the ferricyanide solution so greatly accelerates the process of bleaching. The answer, I take it, is as follows. The ammonium bromide interacts instantly with the slimy deposit of silver ferrocyanide initially formed, giving as the result of the interaction a product which is readily permeable to the bleaching solution. Another lower layer of silver is rapidly converted into silver ferrocyanide, which is instantly acted on by the bromide, permitting of the ready access of the bleach to still lower strata of the silver image. And thus the bleaching is rapidly completed by an alternation of two separate and independent reactions.

If this view of the matter is correct it necessarily follows that rapid bleaching should result from the alternate immersion of the print in pure solutions of potassium ferricyanide and ammonium bromide respectively. This I find to be the case. A print was dipped for an instant into potassium ferricyanide solution (of the same concentration as the bleach) thoroughly washed, and then submitted to a bath of ammonium bromide. Again, the print was washed, returned to the ferricyanide bath, washed, returned to the bromide bath, and so on. Deducting the times required for the intermediate washings, a print thus treated was found to bleach in practically the same time as would be required by the bleach made by mixing the two solutions of ferricyanide and bromide. The final tone of a print bleached by the intermittent method is the same as that of a print treated with the usual bleach.

### The Composition of the Bleached Image.

The next point to be cleared up is this: What is the nature and composition of the product of the interaction of silver ferrocyanide and the ammonium bromide solution? In other words, what is the composition of the final product in the bleached image? It seems to be generally assumed that the final result of the bleaching is the conversion of the silver image into ordinary silver bromide  $\text{AgBr}$ . I think I have proved that this view can no longer be retained.

However long a print remains in the bleach, it is never, literally speaking, bleached. The "bleached" image is always clearly discernible, and has a pronounced brownish hue even when the bleaching operation has been conducted in non-actinic light. But ordinary silver bromide is not brown. If a bromide print is bleached in bromine water (when undoubtedly ordinary silver bromide must be formed) the print is literally "bleached"; it is quite impossible to discriminate between the white image in silver bromide and the white paper which supports it.

Again, a print bleached with the bleach in darkness is readily redevelopable by any of the ordinary developers. But a print bleached with bromine water in darkness must first be exposed to light before it can be redeveloped.

From these two considerations alone it is clear that the bleached bromide print cannot consist of ordinary silver bromide. Of what, then, does it consist? I believe of a hitherto unrecognised sub-bromide of silver, which for the present I propose to distinguish by the non-committal title—the puce-coloured bromide of silver.

Pure, finely-divided silver was prepared by adding ferrous sulphate solution to silver nitrate solution, and then treating the precipitate with dilute acid, and finally washing it. A known weight of this silver was shaken up with the bleach in a stoppered tube. The ferrocyanogen content of the bleach was determined before and after the treatment with silver.\* It proved to be practically the same after treatment as before. Hence I was forced to the conclusion (quite contrary to the expectations and bias I entertained before actually starting my experiments) that no ferrocyanogen

is present in the deposit constituting the bleached image. The deposit must therefore necessarily consist of silver and bromine only.

The puce-coloured body into which the silver is transformed by the bleach was thoroughly washed, dried at 100 deg. C., and weighed. It was then treated repeatedly with warm dilute nitric acid to remove any unconverted silver that happened to be admixed with it, and again washed, dried, and weighed. Thus it was enabled to determine the percentage of silver in the body, and this I found to be some 61 per cent. Since ordinary silver bromide contains only 57.4 per cent., it follows that this puce-coloured body must, in conformity with the usages of chemical nomenclature be regarded as a form of sub-bromide. The puce-coloured bromide prepared as above described has a very high density, sinking in water as rapidly as the silver from which it was formed. It is, like silver bromide, easily soluble both in potassium cyanide solution and in hot solution of mercuric nitrate.

So far, I have made only two preparations and two analyses of this bleach product, and in both analyses only the percentage of silver was determined directly—the percentage of bromine being estimated by difference. I purpose, when the occasion offers, to repeat the analysis with greater care, varying the methods of procedure and making direct determinations of both the silver and the bromine.

To sum up; I conclude that the bleached image consists of a dark puce-coloured sub-bromide of silver, and that hence results the visibility of the "bleached" image.

The puce-coloured bromide would seem to be more readily dissolved by alkaline bromides (potass. and ammonium bromides) than is the ordinary bromide of silver. For if two slips of the same bromide print A and B are bleached, A in potass. ferricyanide containing a fair excess of ammonium bromide, B in bromine water containing the same concentration of ammonium bromide, and the slips are then sulphuretted, it is found that the image of slip A is ever so much more reduced in intensity than is that of slip B. Indeed, an over-developed bromide print may very successfully be reduced and toned at the same time by increasing the amount of bromide in the bleaching bath prior to sulphuretting. In general it may be stated that the greater the concentration of the bromide in the bleach, the colder and more purple is the resulting tone, and the fainter is the picture.

In this connection the point arises whether there is not an unnecessary excess of bromide present in the empiric recipe for the bleaching solution given in the "Almanac." The molecular weight of ammonium bromide is 98, that of potass. ferricyanide is 329. Even if ordinary silver bromide (and not the puce-coloured sub-bromide) were the final product of the bleach, its indirect formation via ferricyanide would demand the presence of only one gramme-molecular weight of  $\text{NH}_4\text{Br}$  to each gramme-molecular weight of potass. ferricyanide. Whereas the bleach made up according to the recipe contains about 3.6 gramme-molecular weights of ammonium bromide per one gramme-molecular weight of potass. ferricyanide. This apparently unnecessary excess of ammonium bromide may (in view of the susceptibility of the puce sub-bromide to the action of alkaline bromides) have a deleterious reducing effect on the faint details of such prints as, prior to toning, are not over dense, but exhibit a satisfactory depth and range of gradation.

It will be noted that I do not yet venture to give the equation showing the *modus* of the formation of the puce sub-bromide from the interaction of the ammonium bromide and the silver ferrocyanide. Much quantitative analytic work must still precede the writing down of such an equation. But it may be of interest to note in passing that I find that alkaline bromides do not produce this insoluble puce-coloured body when, in the absence of any metallic silver, they interact with the bluish ferrocyanide of silver prepared in the ordinary way by double decomposition between a soluble silver salt and a soluble ferrocyanide. The interaction between soluble bromides and ferrocyanide of silver thus prepared is an exceedingly complex one, but is of purely chemical rather than of photographic interest. Suffice it here to say that so far from an insoluble silver bromide being the end result, complex cyanogen compounds of silver, both soluble and insoluble, are formed.

It should be noted that the chemistry of the bleaching process here described is of interest and importance, not only from the standpoint of the toning of bromide prints, but also from the standpoint

\* It may be well to give the outline of the analytic method adopted in this connection. Equal volumes of fresh bleach and of bleach in which metallic silver had been digested were treated with excess of  $\text{NaOH}$ , boiled, and while boiling reduced from the ferricyanide to the ferrocyanide condition by the addition of ferrous sulphate. The reduced solutions were made up to equal bulk and aliquot portions filtered off and titrated with a standard solution of copper sulphate, using filter paper slips dipped in ferric chloride as indicators of the end of the titration. Equal volumes of the  $\text{CuSO}_4$  solution were required both in the case of the fresh and used bleach, showing that the insoluble silver compound formed has no ferrocyanogen content.

the production of carbon prints from bromide prints by Mr. Luby's new and elegant ozobrome process.

### The Sulphuretting of the Bleached Image.

It is generally taken for granted, I believe, that the sulphuretting of the bleached image converts it into ordinary sulphide of silver. It has always seemed to me, however, that the correctness of this assumption is *a priori* improbable. For ordinary sulphide of silver is, to use a colloquialism, "as black as one's hat," whereas the finished toned image varies in hue from brown to sepia. Of course, there is the possibility of the dichroism of silver sulphide as a substance which in bulk is black—might in thin layers be brown or sepia coloured. But I believe I have sufficient proof of the correctness of my *a priori* conclusion that the toned image does not consist of ordinary silver sulphide.

As a sulphuretting agent, I originally made use of the solution of silver sulphide, of the concentration recommended in the "B.J. Manual." But I soon abandoned this solution on account of its poor keeping qualities. The sulphuretting solution which I chiefly use, and which I would recommend to the notice of sulphide toners, is a solution of the sulphhydrate (and not the sulphide) of sodium. This solution I prepared in the following way. Six grammes of caustic soda were dissolved in 250 ccs. of water, and the solution was divided into equal portions. One portion was saturated with well washed hydrogen sulphide, and then added to the untreated portion. A solution so prepared can be used over and over again, and keeps its virtue perfectly for at least six months. Sodium sulphide solution of the strength usually recommended is completely decomposed and worthless for toning purposes in three or four days. In addition to its stability, the sulphhydrate solution also possesses the great recommendation that it has a barely perceptible smell of hydrogen sulphide, so that it may be used in the laboratory or studio without annoyance. When, however, the toned prints are submitted to the action of the wash-water, there is a considerable evolution of hydrogen sulphide from them, and therefore it is advisable to conduct the washing out of doors, or at any rate in a room where fumes of hydrogen sulphide can do no damage to man or material. The tones given by this sulphhydrate solution have a pleasing purplish tinge, and it seemed to me (though I would not venture to dogmatise on the point) that this solution does not choke up the heavy shadows in the picture to the same extent that ordinary sulphide solution is well known to do.

What, then, is the nature of the brown or sepia coloured body formed in the sulphuretting bath? I believe it to be a gelatino-sulphide of silver, probably approximating in its character to the metalbates and lysalates investigated by Paul and Voss. (Abstracts, Chemical Society's Journal, 1902.)

I find that when silver bromide emulsified in gelatine is made

slightly alkaline and then treated with hydrogen sulphide, black silver sulphide is not precipitated, but a dark room opalescent liquid results, which passes through the blue ribbon brand of Schleicher and Schüll's filter paper. (The blue ribbon brand of filter is guaranteed to strain off the finest and most refractory precipitates met with in analytic work.) Or, again, if plates which have been exposed, developed to the utmost, fixed, and then submitted to sulphide toning in the usual way are treated with boiling water, the same brown opalescent solution, from which no solid can be filtered off, is obtained. This brown "solution" of gelatino sulphide of silver is not affected by large dilution, nor is it in any way coagulated or precipitated by the addition of either alcohol or neutral salts. (On long standing, however, it deposits small quantities of a dark brown solid.) Hence, I infer that it is not an ordinary colloidal solution, but that it is in all probability an exceedingly fine emulsion of extremely small solid particles—that it is, in fact, a quasi-solution of the type studied by Picton and Linder. (Chemical Society's Journal LXL.) If this is the correct conclusion, the very finely divided suspended solid would probably be separable by filtration under pressure through a biscuit-ware porous cell, and the "solution" itself should be capable of polarising light. These possibilities will be made the subject of further investigation.

The brown "solution" of gelatino sulphide of silver is decomposed when boiled with nitric acid, a light khaki-coloured precipitate being thus thrown down. This precipitate contains both sulphur and silver, since when treated with a mixture of hydrochloric acid and potassium chlorate, silver chloride is formed, and the filtrate gives the  $\text{SO}_4$  reaction with a solution of barium salt; it is, therefore, some new form or new modification of silver sulphide.

I have seen it stated somewhere that bromide prints which have been thoroughly dried are not amenable to the sulphide toning process. My own experience renders it difficult for me to conceive how such an idea could ever have arisen. For most of my experiments have been made with prints of several months' age, and I have never met with a single case of refusal to tone.

In the course of my experiments I have tried various suggestions that I have seen made with a view to increasing the transparency and detail—rendering in the heavy shadows of toned prints by means of water-lac varnishes. My experience is that very little, if any, virtue lies in these suggestions. A diluted spirit varnish undoubtedly does clear up and brighten the picture, but it is difficult to apply this varnish so as to show no streakiness. If bright, transparent, toned prints are desired, it seems to me best to use papers of the enamel type. In conclusion, I may state that all my work has been carried out with only one make of bromide paper—the Wellington.

DOUGLAS CARNEGIE.

## PHOTOGRAPHY IN THE WORK OF GREENWICH OBSERVATORY.

The Ninth Traill-Taylor Lecture.—Concluded from page 930.

### Connection between Solar Activity and Terrestrial Magnetism.

There is a very marked periodicity in the average extent both of the sunspots and of the whole spots in a period of about eleven years. There was a well-marked maximum about the end of 1883, and another about the end of 1893, while 1878, 1889, and 1901 were years of very small sunspot activity indeed.

Not only is the period of variation the same for the solar and the magnetic phenomena, but the times of minimum for the one curve are the times of minimum for the other; and so for the times of maximum. Here, therefore, we have evidence of a real connection between solar action and terrestrial magnetism.

The photographs have further shown us what are the characteristic forms most usually assumed by solar spots. The type of group which most frequently attracts attention begins its life as a single small dot on the surface, which is usually very quickly joined by a second close to it. These two small spots then pass, through a short period of rapid growth, and as they grow they move away from

each other, the line of motion being generally nearly, but not quite, parallel to the solar equator, and the rate of motion apart being about 8,000 miles a day. The two spots are at this stage very unlike each other in appearance, the preceding spot being usually nearly circular, with a strongly marked and regular outline, and a very dark and circular umbra in its centre. The second spot is much less regular in form; its umbra is often neither central in position, nor so dark, nor so symmetrical as that of the first spot. The symmetry of the second spot is largely impaired because, between the two spots there is a specially bright region from which bright streamers extend to invade or even cross the following spot. At this period in the history of the group this intermediate bright region is stippled with a number of small irregular spots, suggesting by their position and appearance that they are portions of a great structure, glimpsed by chance through random interruptions in a bright cloud formation above them.

The next stage in the spot's history is the disappearance of the small irregular spots in this middle region until the group is reduced

to two large and widely separated members, the original first and second spots. Of this pair the following member soon disappears, and the original leader remains alone, sometimes even for weeks. This leader sometimes breaks up into fragments, but more frequently slowly fills up from the circumference inwards.

All groups do not conform to this type. The very largest are generally of quite a different form and behave in a different manner. We may, however, leave their characteristic development on one side in the present connection, and draw attention rather to the frequency with which these abnormally large spots have synchronised with the occurrence on the earth of remarkable magnetic storms. Thus, in the year 1882, three great sunspot outbursts—two in April and one in November—each synchronised with a great magnetic storm. Ten years later the largest spot observed during a quarter of a century appeared, and again we experienced a great magnetic storm. This great spot was carried by the sun's rotation out of sight at the west limb, and then by the same means was brought into view a second time at the east limb. It was now rapidly decaying, and was greatly shorn of its former proportions. But—and this is the remarkable circumstance—directly the group had a second time reached the apparent position on the sun's disc that it had held at the time of the beginning of the first magnetic storm, a second storm broke out almost as intense. From this and from similar events we have reason to conclude that there is not only a general connection between sunspot activity and the variations in terrestrial magnetism, but also often a specific connection between special spot groups and special storms.

#### Photography in Solar Eclipses.

There is another form of research, which, though not carried on within the Observatory, has been carried on from it, in which photography has been of the very highest service. This is the observation of the corona. We are, of course, unable to see this beautiful and mysterious halo, except when a total eclipse of the sun is in progress. At such times there is an immense deal of work to be done in but a few seconds of time. The eye and hand, however carefully trained in artistic expression, fail to record in the very short space of time available anything except the most prominent features, and it is not possible to rely even upon these with entire confidence even in the very best drawings. As to the immense wealth of detail shown by the corona from time to time, this must go entirely unrepresented by this method.

Here, then, we have a necessity which is exactly one that photography can meet: the photographs can give us what the eye cannot, the multiplicity of forms in their relative positions and with their relative intensities. And we can rely on the photograph; we can compare the corona as seen in one eclipse with that seen in another; and in any given eclipse we can compare the corona as observed from two different stations.

Greenwich Observatory did not take any lead in this application of the photographic method, because eclipse work was at one time considered as outside its programme, so though De La Rue had Greenwich programme. From that time onward there has been regularly employed in 1870 and the subsequent eclipses, it was not until 1886 that Greenwich Observatory sent out an expedition equipped for photography, nor was it until 1896 that eclipse observation can be said to have been thoroughly included within the Greenwich programme. From that time onward there had been an effort to take advantage of every suitable opportunity to secure photographs both of the corona itself and of its spectrums with instruments of two or three well-defined standard designs, so as to secure records as far as possible comparable with each other.

There are, as you know, great difficulties attending coronal photography. The corona presents us with a structure varying extraordinarily in the brightness of its different parts, and much of it filmy, indefinite, and diaphanous. So far as my experience goes, the corona is absolutely the most difficult object for satisfactory representation in a photographic illustration. As I pointed out when I had the honour of addressing you some seven years ago on "Exposures in Coronal Photography," "the problem before us is to secure a record of a most complex object of which the brightest portions can scarcely be less than ten thousand times the brightness of the faintest." Many attempts have been made to get over this difficulty by one or other of several indirect means, such as the use of mechanical devices for screening the inner and brighter portion

of the corona from acting on the sensitive plate during a considerable portion of the time that the latter is exposed to the outer faint regions. In the expeditions sent out from Greenwich, however, the method has been generally adopted of giving a great variety of exposures to different plates, and frankly facing the certainty that no one plate will show the corona satisfactorily throughout its entire extent.

After the expedition has returned, the photographs secured have been handed over to Mr. W. H. Wesley, an astronomical artist, whose skill and experience in this department are unrivalled; and he, in the most careful scrutiny of all the negatives prepares a composite picture, in which the details shown on each of the negatives are represented.

The Greenwich Photographic Eclipse Expeditions have been sent out in number, 1886, 1887, 1896, 1898, 1900, 1901, and 1905. Completely frustrated the efforts of the observers in 1887 and 1896, of one of the parties sent out in 1905. The remaining expeditions were thoroughly successful.

In 1886 the existence of "white prominences" was detected; previous to that year only the rose-coloured prominences were known. In 1898 the method in which the great synclinal structures of the corona is built up was clearly demonstrated, and the emission of the sun of long straight rod-like rays ascertained. The 1900 expedition afforded a striking example of a regular quiescent corona, the type of the form assumed by the corona at the sun spot minimum, whilst 1905, on the other hand, supplied an example of a corona of extreme disturbance, the very type of the corona at the sun spot maximum. 1901 gave a result more interesting still, for Greenwich sent out two expeditions in this year, the one to Mauritius and other to Sumatra; and the observations at the two stations were separated by nearly an hour and a half of absolute time. The comparison of the photographs gave for the first time clear, definite, and unmistakable evidence of changes having taken place in the corona during the progress of a single eclipse; a result which, it is needless to say, could never have been obtained except by means of photography.

#### Photographs of Nebulæ and Comets

There are other departments of astronomy in which the power of the sensitive plate to depict at one time an infinite number of details has proved of enormous value. But for the most part these do not fall within the Greenwich programme. The magnificent survey of the surface of the moon carried on at the Observatory of Paris is an example of one such work; the studies of nebulae by the late Isaac Roberts another; and the wonderful explorations into the regions of the Milky Way, by Professor E. E. Barnard, a third. A few photographs of each order have indeed been taken at Greenwich, but rather as a training and test of the observer's skill than in pursuit of any definite research.

The case is a little different when we come to comets. With regard to the structure of these mysterious wanderers, photography may truly be said to have opened for us a hitherto sealed volume. In the case of objects of this character, faint and extended, the increase in the size and power of the telescope was not always an advantage for eye observation. It enabled, indeed, a higher magnification to be used, but higher magnification was not what was required; was greater intensity of light. With photography, however, greater intensity could be obtained in two ways—either by increasing the aperture relatively to the focal length, or by prolonging the exposure. Both these expedients are employed at Greenwich; a reflecting telescope of 30 inches aperture and 11½ feet focal length being usually employed upon comets and nebulae, whilst exposures of an hour and upwards are made when necessary. And as the result, we see that comets, which to the eye at the telescope would have shown hardly any perceptible structure, in the photograph present us with a well-marked series of distinct tails, and in some cases with distinctances of the tails of a most remarkable and significant character.

#### Photographs for Measurement.

The subject of comets leads me naturally to the third division of my subject, the use of photography for the determination of positions. For the study of cometary forms is not one of the regular items of the work at Greenwich, but the determination of the places is. It is, of course, a very natural step to take, that when we have the telescope, the observer, and the sensitive plate all ready

to take a short exposure photograph of a comet in order to determine its position, we should also expose a second plate for a longer time in order to get an information as to the physical structure of the comet which direct scrutiny could not give us.

It is in this third division of my subject that we come to the services which photography has rendered in work lying within the original programme of Greenwich Observatory. That programme was "the rectifying the tables of the motions of the heavens and the places of the fixed stars." The formation of exact catalogues of the places of the stars, and the observation of sun, moon and planets in their apparent movements amongst them, lay within the express terms of the warrant appointing the first Astronomer Royal. And though the original purpose of its foundation was a purely utilitarian one, namely, to develop practical navigation, the progress of the science of astronomy has carried it far beyond the limits of the necessities of that purpose, yet the words of the original warrant still define the chief duties of the Observatory.

Thus it was that when the scheme was set on foot of a great international project for photographing the entire sky on a scale which would give us a catalogue of the places of over three million stars, and a map showing perhaps twelve or fifteen times as many, Greenwich Observatory could not but take its part in the scheme. This is much the largest photographic undertaking in which Greenwich Observatory has a share, and both from the magnitude and importance of the undertaking itself and from the many important problems which it has raised, it might justly claim first consideration in my present paper. But the subject has already been dealt with before you, so fully and by so competent an authority, in the fifth Traill-Taylor memorial lecture delivered before you in December, 1902, by Professor H. H. Turner, of Oxford, that it would be superfluous for me to take up the subject again. In Professor Turner's words "a great work is being carried out from which we may expect great results, a work scarcely dreamt of thirty years ago—to-day not only possible but comparatively easy of accomplishment."

Leaving, therefore, the great photographic star map on one side, not because it is not of first importance, but because it has already been so thoroughly dealt with here before, I may point out that an important by-product of the scheme at Greenwich was that we became aware that in photography we had a method of saving not a little time and labour in many determinations of place. Thus, for example, many hundreds of minute bodies revolving round the sun between the orbits of Mars and Jupiter are now known. Most of these are extremely faint, and are in no way distinguishable from stars by their appearance. If it is desired to make a direct observation of one of these, both its position and those of the stars amongst which it may happen to be at the moment must be known with the greatest precision before it can be identified, and then it must be watched for a considerable time before the identification can be confirmed by seeing that it moves with respect to the neighbouring stars. In the case of the photographic plate there is no such trouble. The standard plate of the International Chart covers an area twenty times as great as the disc of the full moon. It is therefore quite easy to secure that the desired "minor planet" should be on the plate and, indeed, near its centre. And we discriminate it from the stars most readily. Let us make four exposures on a single plate, moving the telescope between each so that the four images of any one star occupy the four angles of a neat little square. Then if we examine the photograph after development we shall find one of our squares distorted, and we know that the four images there shown must be those of our minor planet, the distortion being caused by its movement relative to the stars.

There is, therefore, an immense saving in time and trouble by the substitution of the sensitive plate to the observer's eye. Much of the work which previously had to be done at night at the telescope, subject to all the interruptions arising from cloud, bad definition and the like, can now be done at leisure in daytime in the computing room, and with the unforeseen result that a single measure made on the photograph is found to be fully as accurate as a single measure made at the telescope. There is, of course, the further great advantage that measures thus made are not only less liable to accidental errors of reading and the like, but if any doubt arises they can be repeated with the greatest ease.

Most of the minor planets have but very little interest for us. They are searched for and followed in the hope that one in a hundred,

or one in five hundred, may have an orbit which will render it of special service to us. The one in five hundred which we have found is the planet Eros, which comes at times much nearer to us than any other celestial body except the moon. Venus at its nearest approach is more than twenty-three millions of miles away from us; Eros at its nearest approach is only seven millions of miles away. Venus from many reasons is a specially difficult object to observe; its brightness, the size of its disc, its nearness to the sun, all constitute hindrances to exact observation. Eros, at its brightest, may conceivably be just visible to the naked eye, and is a mere point of light. In many ways, therefore, its distance can be much more readily measured than that of any other of the planets, but when the distance of one planet of the solar system is known, those of all the others can be deduced from it, so that Eros offers us one of the best means of ascertaining the exact mean distance of the sun—the exact scale upon which the solar system is built.

#### Measures of the Places of Faint Satellites.

The same method has been employed for studying the orbits in which the satellites of some of the planets of the solar system revolve round their primaries. In particular there may be mentioned the case of the satellite of Neptune, a difficult object for direct observation on account of the faintness of the satellite and the comparative brilliancy of its primary. But the photographs, taken during three oppositions at Greenwich, proved sufficient to give distinctly improved elements of its orbit. The difficulty of the great relative brightness of Neptune was overcome by the use of a small occulting shutter, which concealed the planet during the greater part of the time that its satellite was exposed.

The instrument used for photographs of this character is a fine refractor 26 inches in aperture specially corrected for photography, constructed by Sir Howard Grubb, and presented to the Observatory by the late Sir Henry Thompson. It is carried by the same mounting as the Thompson photo-heliograph and the 30-inch reflector.

Yet more interesting has been the case of the new satellites of Jupiter and of Saturn. The sixth and seventh satellites of Jupiter were discovered by means of the Crossley reflector of the Lick Observatory of California. They are both very small objects, their probable diameter in miles being only about 100 and 35 miles respectively and their stellar magnitudes 14 and 16. They are so faint and at such a great distance from Jupiter that they could never have been discovered by direct observation; they show themselves on the photographic plate by appearing as nearly circular dots when the camera is made to follow Jupiter, whereas stars show as short trails. The Lick astronomers concluded that they were too faint ever to be observed by means of any of the Greenwich instruments, but experiments have shown that an exposure of seventeen minutes is sufficient to record the fainter of the two, and the Greenwich photographs are sufficient for the orbits of both to be determined from them. These orbits have some very striking peculiarities; the two satellites are nearly at the same distance from Jupiter, and they move in the same direction as the five inner satellites, but their orbits are very strongly inclined to each other and to both the orbit and equator of their primary.

#### Measures of Positions of Sunspots.

There is yet one other department in which photography has served for the determination of positions. The photographs taken of the sun are used not only for ascertaining the numbers and areas of sunspots, and for watching their growth and decay, but also measuring their positions on the sun's disc, their solar longitudes and latitudes. From these measures are derived, not only the mean rotation period of the sun for those latitudes in which sunspots appear, but they also bring into prominence several remarkable features. First of all the proper motions of spots vary remarkably—that is to say, groups move to and fro on the solar surface with a quite astonishing rapidity, the movements in extreme cases amounting to 12,000 miles per day. Next, the mean rotation period, as derived from the sunspots, increases as we recede from the equator. And thirdly, the spots affect different zones of the sun's surface at different times of the sunspot cycle. Just after the minimum, when they are first beginning to increase in number, they are confined to high latitudes, and from this time onward, through the period of increase, through the time of maximum activity and through the subsequent decline, there is a general

decrease in the latitude of the spot-active zones, until just before minimum the spots are nearly wholly restricted to the equatorial region, but before the actual minimum is reached, before the spots of the old cycle have entirely disappeared, a few spots begin to appear in high latitudes, harbingers of the new cycle just commencing.

With these results derived from the measures of the Greenwich sun-pictures, I should wish to conclude this very hasty summary of the third division of my subject—the use of photography in measures of position. But some of these results have a very direct bearing upon that circumstance which I noticed in the earlier part of my lecture, namely, that the photographic registers of magnetic disturbances show that such disturbances have a strong tendency to recur at intervals of about 27½ days. For this interval is none other than the mean synodic rotation period of the sun as derived from the observation of sunspots. The actual rotation of the sun on its axis is 25.2 days in length, but as the earth in its orbit travels in the same direction as the sun rotates, it is 27½ days before the same part of the sun's surface comes a second time to the centre of the sun's disc as seen from the earth. So striking is the connection between this synodic period and what may be called the recurrence period of the disturbances, that in one instance no fewer than eight storms followed each other in a succession as the same solar longitude made its successive returns to the centre of the disc.

#### The Sun's Far-reaching Tentacles.

Such a synchronism is unmistakable evidence that the provoking cause of the disturbance depended for its coming into operation upon the successive presentations of one and the same region of the sun under the same aspect towards the earth. This shows that in these disturbances we are not dealing with the result of any general radiation from the whole of the sun's surface, because such action would be continuous. Nor is the action of the nature of a radiation equally in all directions as is the case with the sun's light and heat, for if it were the effect would begin to be felt at half a rotation period from the expiration of the previous disturbance, since any region of the sun is only in the invisible hemisphere for about a fortnight at a time. The solar action, therefore, giving rise to the disturbance, takes place, not from the sun as a whole, but from restricted areas of it, and is not a radiation in all directions, but an emission in a particular direction. The recurrence, therefore, of magnetic disturbances at intervals of one or more synodic rotation periods of the sun, shows us that the earth has encountered time after time a definite stream, whatever

be its character or composition, a stream which continually supplied from one and the same area of the world's surface, appears to us at our distance to be rotating at the same speed as the area from which it rises.

Therefore, we now know that not only is the sun continually throwing off in all directions enormous energy in the form of light and heat, it also stretches out enormous tentacles in specific directions through space, in the form of these stream lines which reach us right across the immense gulf of ninety-three millions of miles. These stream lines overtake the earth in its orbit, and therefore, if they encounter it, and do not pass above or below it, they strike it first upon the sunset arc—that is to say, upon that half-circle of the earth's surface where the sun is seen as just setting.

This is a new conception in solar physics, and without doubt ere long it will carry us to an unexpected solution of many problems now obscure.

But it is not my wish on the present occasion to indulge in prophecy; I will only ask you to note how the three purposes for which photography has been employed at Greenwich here unite to give us a complete picture. The continuous registration of the movements of the magnets gave us the all-significant interval relation between the disturbances. The measures of position on the solar photographs gave the rotation period of the sun which explained that interval relation, and demonstrated the existence of these great stream lines. The pictorial photographs taken of the corona have shown the origin in the immediate neighbourhood of the sun of actual stream lines analogous to, if not in some cases the very same as those which, striking the earth, disturb its magnetic equilibrium.

#### Conclusion.

I have now attempted to give you some outline of several of the chief services for which our work at Greenwich Observatory is indebted to photography, and I trust I have so far succeeded in my task that you will agree with me that great indeed is our obligation to those who invented and improved the various photographic methods. It is, indeed, in order to give some slight expression to the gratitude which we ought to feel and do feel towards photographers that I am here this evening. On the other hand, as a member of the Greenwich staff, I feel that the record of the use which we have made of photography is not one for which we need to blush. A powerful weapon has indeed been put into our hands, but I trust that what I have been able to say this evening will show that we have neither suffered it to blunt nor to rust, nor have used it unworthily.

E. WALTER MAUNDER.

## THE BRITISH JOURNAL ALMANAC, 1907.

TO-DAY (Friday) the forty-sixth volume of the "British Journal Photographic Almanac" is obtainable throughout the United Kingdom. The character of the "Almanac" and the ways in which it has been brought in line with recent progress in photography have been kept before our readers prominently within the last month or so, but it may nevertheless be permitted us to offer a brief glance over the volume which to-day is on sale.

In addition to its directories of photographic societies and other photographic associations, national and otherwise, the "Almanac" brings together a collection of facts and formulæ which are to be found in no other volume, and it must be remembered, too, that the commercial announcements which appear in the "Almanac" amount to the possession on the part of an almanac-purchaser of the catalogue of almost every photographic firm of standing. The money which would be expended in obtaining the price-lists of these firms would amount to several times the price of the "Almanac"—in other words, the "Almanac" affords the unique experience of seeing at a glance the manufactures of the whole photographic trade, and thus constitutes itself a market-place of the world for photographic goods wherein every conceivable article may be found and purchased.

No less encyclopædic in its character is the text portion of the "Almanac." The editorial article this year deals with photographic processes for the making of three-colour prints on paper, a branch

of work which is, perhaps, attracting as much attention at the present time as any department of photography. This article deals with the carbon, pinatype, gum, imbibition, and bleach-out processes, and others from the point of the practitioner.

Among the contributed articles which have been a feature of the "Almanac" from its commencement are the following, among others:—

"An Amidol Developer to Keep," by Mr. C. Welborne Piper.

"Development by Reflected Light," by Mr. G. T. Harris.

Mr. G. R. Ballance has a note on reducing and clearing platinum types.

Mr. A. J. Newton, of the Bolt Court School, contributes a valuable article on the use of the different orthochromatic sensitizers, selecting only those which have been found successful in use.

An interesting note on exposing bathed plates wet is contributed by Dr. Edmund J. Mills, among other "practical hints."

Mr. Victor Selb writes of stereoscopic separation, and a reader of the "Almanac" in the Far East, Mr. H. G. Ponting, of Tokio, contributes a description of the method, devised by him and possessing certain novel features, of timing photographic shutters.

An appeal to plate-makers for fewer brands of plates appears from Mr. Alfred Watkins, and Mr. E. Grills describes two modifications of the pinatype process.

These items do not exhaust the contents of the contributed articles,

they will serve to give an idea of the character of the communications to the "Almanac."

Under "Epitome of Progress" the photographic work of the year is brought within the capacity of the average busy reader. To thus reserve what has seemed deserving of that care has been a labour which possibly few readers of the "Almanac" appreciate, but the reward is a reward for those who have expended time and thought on the selection and classification of those papers and articles which have appeared in the photographic periodicals of every country since the "Almanac" of 1906 was sent to press. The scope of these abstracts can best be seen by referring to the headings under which they are arranged:—

- I.—Events of the Year; Copyright; Business; History.
- II.—The Dark-room and Studio.
  - Lenses and Photographic Optics; Optical Glass, Properties of Lenses, Lenses in Practice.
  - Telephoto Lenses.
  - Lens Testing and Measurement.
  - Cameras and Accessories.
  - Instantaneous Shutters.
  - Artificial Light: Enclosed Arc Lamps, Magnesium Light.
  - Materials: Raw Paper, Tests of Paper.
- III.—Portraiture, Landscape.
  - Copying.
  - Stereoscopic Photography.
  - Pinhole Photography.
- IV.—Gelatin-bromide: Backings, Emulsions.
  - Orthochromatic Processes: Sensitisers, Light-filters.
  - Development: Developers, Time Development, Stand Development, and Methods, Defects, etc., in Development.
  - Self-developing Plates.
  - Fixing and Hypo Eliminators.
  - Intensification of Negatives.
  - Reduction of Negatives.
  - Varnishes.
  - Retouching Negatives.
- V.—Positives Direct.
  - Printing Methods and Accessories.
  - Gelatine and Collodion P.O.P.; Emulsions; Toning, Developing.
  - Self-toning Papers.
  - Bromide and Gaslight Papers: Warm Tones by Development, Toning Bromides.
  - The Carbon Process.
  - Ozobrome.
  - Gum-bichromate: Multiple Gum.
  - Oil-printing.
  - Platinum Printing.
  - Iron Printing Processes: Ferro-prussiate, Copying Tracings.
  - Catatype Printing Processes.
  - Miscellaneous Processes and Prints on Various Supports.
  - Mountants and Mounting.
  - Enlarging.
  - Working-up and Colouring Prints and Enlargements.
  - Lantern Slides, Cinematography.
- VI.—Direct Interference Processes (Lippmann).
  - Bleach-out Processes.
  - Three-colour Processes: Apparatus, Plates, Filters, and Sensitisers.
  - Transparencies by the Indirect Three-colour Process.
  - Three-colour Processes on Paper.
  - The Diffraction Process.
  - One-plate Three-colour Processes.
  - Two and Four Colour Processes.
  - Colour Effect from Ordinary Negatives.

Lastly, we must not omit to mention the reviews of recently introduced apparatus, the only drawback to which is the regrettable fact that so little that is new in the way of apparatus has been placed on the market.

Also, the "Almanac" contains the formulæ for the use of the various photographic materials on the market, a section which has been brought up to date, and represents the departures made within the year by a number of makers.

Other features of the volume are no doubt well known to its regular readers, but we may be excused for having pointed out some salient features of the issue which has now been published, and of which, so far as we can judge at the time of writing, the whole supply will be exhausted before complete publication.

#### "G. B. S." ON ART IN UTOPIA.

LECTURING at the Essex Hall, Strand, last week, under the auspices of the Fabian Society, Mr. G. Bernard Shaw had something to say on what may be called the commercial ethics of art, including portraiture. His subject was "Socialism and the Artistic Professions," and the many questions raised in considering such a subject must—politics apart—have an indirect interest for photographers, professional and amateur. Mr. Shaw's point of view is well known. He is a Fabian idealist who is most emphatically not a Philistine, and he recognises that while an "ideal" State would have to acknowledge the importance of the artist, it could not very well fix his remuneration on any cut-and-dried principle. The practical commodities of every-day life cannot be used (or, rather, consumed) over and over again; pictures, like books, can on the other hand, be enjoyed for generations and generations. So, says Mr. Shaw, it comes about that the artist is in a peculiar position, and you cannot arrange for his remuneration, as you would for that of the baker. The matter, of course, hinges on copyrights and royalties, and the lecturer pointed out that this property of the artist in his art is a comparatively recent institution, much younger than the property in land and other things. It is, moreover, strictly limited, for it cannot be held perpetually. At the end of so many years books and plays "went into the common stock" of the country. Here, presumably, is a principle applying equally to pictures and reproductions. He had to admit that the economic problem of art was still very far from being solved. A State run on Communistic principles might choose between allowing copyright to remain as at present and itself purchasing copyrights. As things were now, the artists whose work happened to please the fancy or flatter the vanity of rich patrons were able to make large sums of money, while others, who perhaps worked with more sincerity and zeal for their art, suffered neglect. A man who found a successful groove was strongly tempted to remain in it and produce works to satisfy a popular market demand. Year after year the Royal Academy showed this influence to be operative. Mr. Shaw turned to portraiture for an example of the unequal division of the world's prizes and luxuries. The fee of the successful and ultra-fashionable portrait painter might run to £2,000; while one might get a portrait of oneself in the form of ferrotype at from a penny to sixpence. Many of the pennies and sixpences thus paid might involve a much greater sacrifice in proportion to means than the fee to the fashionable painter. In a community governed according to Fabian ideas, he anticipated that the sources of enormous incomes for artists would vanish, but with a widening of the comforts of life would also come a higher general standard of artistic taste, and therefore a greater demand for pictures and the works of craftsmen. The question was important because of the enormous part played by the arts in forming the human mind, and Mr. Shaw was unable to agree with the suggestion of a questioner in the audience that in a Utopia people would be able to provide for themselves in their leisure time all the objects of artistic interest they needed. That is what may be termed the Philistine solution of the question. They might, replied the lecturer, be able to interest themselves, but he was not sure whether they would interest their friends. He added, with emphasis, that the great artist, in any department, must be the man who had specialised for years. Early in the lecture he pointed to what he thought was an obvious fact, that much of our modern painting came from the "gentleman amateur." It lacked what might be called the "trade finish," clever though it very often was, and it did not compare favourably with, say, the paintings of Hogarth. Perhaps if he were pressed Mr. Shaw would say something to the same effect about modern photography.

The death is announced of Mr. H. A. Mortimer, photographer, of Llanwrtyd, at the age of seventy-five.

## MR. J. T. SANDELL—AN APPEAL.

THE total sum of donations to the fund started by Messrs. Thos. K. Grant and J. B. B. Wellington now reaches over £160, this amount including contributions sent to the above gentlemen direct or through the photographic journals. We hope that further donations will raise the total to £200, and would ask those who have read our previous comments on the necessitous condition in which Mr. Sandell is now placed not to allow the fund to be closed without adding a donation to it. We have to acknowledge the following contribution: J. C. Burrow, 2s. 6d., and also to announce the donation of the North Middlesex Photographic Society (per H. Stuart, president), £4 15s., making, with the amount already acknowledged of £129 12s., a total of £134 9s. 6d.

## Photo-Mechanical Notes.

## Curved Process Blocks.

ACCORDING to a recent patent (No. 26,715, 1905) of William Francis Cooper, 7, Grosvenor Road, Watford, a piece of apparatus is to be used for printing from film screen negatives on to curved sensitive metal plates, the blocks thus obtained being for use in rotary machines. The printing device provides for the film negative being tightly stretched over the metal plate, and consists of a frame, *c*, carrying screw bolts, *d*, bearing against strips, *e*, fitting a rectangular

frame, *f*, and adapted to firmly grip the celluloid plate, *b*, carrying the negative. The sensitised plate, *a*, is placed on a die, *g*, of the same shape as the printing cylinder, and the die forced against the celluloid by the tensioning screw, *h*. The sensitised plate is thus pushed out against the negative and when sufficient strain is applied the sensitised surface of the plate and the negative are in optical contact and printing can be effected in the usual way.

## Direct Photo-Lithography.

According to the process for which patent rights have been taken out by Cyrus John Hackett, Hedley Street, New Basford, Nottingham, copying is done direct on to the stone or plate, which is prepared first with a solution of black enameloid, a proprietary article consisting, presumably of asphaltum, next with a coating of bichromated gelatine or albumen, containing also a little shellac rendered soluble in borax. After exposure the stone, or plate, is rinsed for a time. Then removing all the upper portion of the film, which leaves the negative of the subject clearly defined, the unremoved portion of the film is left embedded in the stone or other surface used. This result is produced by the light penetrating through the transparent portion of the negative, and, acting on the film, fixes that portion, which is the negative of the subject, firmly in the pores of the stone, all the other portion of the film being entirely dispensed with, and brushed, or washed, away as before stated. (The aforesaid "negative" repelling the greasy nature of printing ink, the copy of the subject is actually printed from the clear portion of the stone, or other surface used, which is the "positive.")

According to the specification (No. 21,120, 1905), the surface is then rinsed with boiling water, allowed to dry, and rolled up all over in black printing ink, adding a little transfer ink to it, and allowing it to stand a short time. Then, washing off the bulk of the ink with a solution of one part camphor to two parts resin, dissolved in methylated spirit and a little of the turpentine solution before mentioned, the face of the stone is rubbed smooth, the parts not required

cleared with gum and whiting, and the subject is then rolled up printer's ink and etched in the usual manner.

## Commercial Considerations in Photo-Engraving.

At the L.C.C. School of Photo-engraving and Lithography the principal lectured on this subject on Thursday in last week crowded audience of employers, managers, and men. The lecture embodied the results of an extensive enquiry for information as to how photo-engraving work was sold, and what it cost to produce. Detailed items of these costs were shown with great completeness, also particulars as to wages earned here and in America by men engaged in the various departments. A number of suggestions were made by Mr. Newton as to how economies could be effected as production increased. The lecture was followed by a number of slides, showing various systems of cost and time-keeping, and also by a good discussion, which was kept up until a late hour. The interesting lectures, which are free to anyone in the trade, are announced in our columns under the heading of "Meetings of Societies."

The following patents were applied for recently:—

HALF-TONE SCREENS.—No. 25,384. Improved method of sealing glasses for half-tone screens and the like. Sidney Littlejohn, 10, Farringdon Road, London.

HALF-TONE BLOCKS, No. 26,012.—Improvements in the method of production of photo-engraved half-tone blocks. Donald Cameron Swan, 116, Charing Cross Road, London.

## Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

The following applications for patents were made between November 12 and 17:—

PRINTING.—No. 25,613. Improved photographic printing apparatus. Harry William Harold, 155, Queen Victoria Street, London.

MAGNESIUM LAMPS.—No. 25,653. Improved magnesium lamps for photographic purposes. Filip Kratz and August Rathgeber, 12, Gitchnerstrasse, Berlin.

NET FOR PHOTOGRAPHY.—No. 25,662. Framed net for photographing. Benjamin Harry Williams, 12, Castle Street, Dudley.

DRY PLATES.—No. 25,728. Improvements in the manufacture of photographic dry plates. Louis Husson and André Frederic Bornot, 7, Southampton Buildings, London.

SHUTTERS.—No. 25,741. Improvements in focal-plane and other roller blind shutters. Arthur Lewis Adams, 26, Charing Cross Road, London.

CINEMATOGRAPHS.—No. 25,798. Gates for protecting the films of kinoscopes. Leon Lipman Borris, Fife House, Kingston-on-Thames.

PHOTO-TELEGRAPHY.—No. 25,818. Photo-telegraph. Gerlar Christian Geisler, 16, Colebrook Row, Islington, London.

TONING BATHS.—No. 25,869. Improved agent for fixing photographic images. A. G. Bloxam, for the Actien-Gesellschaft für Anilin Fabrikation, Germany.

VIGNETTES.—No. 25,880. Improvements relating to photographic vignettes. Philimon Makeeff, 7, Southampton Building, London.

EMULSIONS.—No. 25,906. Improvement in emulsion for photographic purposes. Otto Pfenninger, 105, Hythe Road, Brighton.

COLOUR PHOTOGRAPHY.—No. 25,907. Improvement in apparatus for colour photography. Otto Pfenninger, 105, Hythe Road, Brighton.

COLOUR PHOTOGRAPHY.—No. 25,908. Improved mirror box for photography in colours. Otto Pfenninger, 105, Hythe Road, Brighton.

## COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

NEGATIVE HOLDERS.—No. 22,469, 1905. The invention is intended

to apply to negative holders for enlarging apparatus, and consists of a carrier frame made to move, in a circular movement, so that its rotating movement allows of the negative being placed at any desired angle in the plane of the holder. William Tulliffe Turner, John William Turner, and Robert Hope, 17, Beaumont Street, Liverpool.

**PIGMENT PAPER.**—No. 14,435, 1906. This invention relates to a photographic pigment paper so made that at the beginning of the development the original support of the pigmented layer, generally paper, can, under all conditions, be easily separated from the pigmented layer. When the latter is transferred to another, temporary or final, support without carrying away with it parts of the pigment contained in the pigmented layer and thus giving rise to faulty places or even gaps in the picture, and that notwithstanding this easy separation the pigmented layer will not float off its original support in cold solutions.

For this purpose between the pigmented layer and its original support there is an intermediate layer which, under all conditions, remains soluble in warm water, so that it dissolves after the pigmented layer has been transferred to a temporary or final support in developing the picture, and thus allows the original support to be removed with ease. Such intermediate layers are well known; indeed, they have been made of the very material most advantageously used according to the present invention, namely gelatine, glue, gum, or the like.

According to the present invention there are added to the gelatine glue or the like constituting the intermediate layer, one or more substances which transform into alkaline monochromate the alkaline bichromate, which is absorbed by the intermediate layer during the process of sensitising the pigmented layer. It is known that a mixture of a normal chromate and gelatine or glue is 20-50 times less sensitive to light than bichromated gelatine is under like conditions.

In a sensitised pigment paper thus prepared, therefore, the alkaline bichromate required for producing the picture exists in the upper layer, while in the intermediate layer such bichromate has been absorbed by the layer has been converted into monochromate. Since the pigmented layer is only exposed to light long enough to produce the picture, the light which penetrates to the intermediate layer cannot render the gelatine insoluble because of its much greater insensitiveness. This layer remains, therefore, practically completely soluble in warm water.

Sodium carbonate is particularly suitable for converting alkaline bichromate into chromates. Other alkaline or basic substances also serve, such as magnesia, borax, sodium phosphate, and water glass.

The pigment paper made according to this invention has the advantage over existing papers having an intermediate layer that this layer may be considerably thinner than the coloured layer, as there is no question of absorbing the light, and the conversion of the bichromate into chromate by sodium carbonate, for instance, can occur in quite a thin layer. Such a layer, therefore, need not be thicker than 0.03—0.04 mm.—thus saving between two-thirds and three-fifths of the material for the intermediate layer.

The following recipes yield suitable intermediate layers for this invention:—

- (1) 100 c.c. of water  
100 grams of hard gelatine  
20 grams of crystallised sodium carbonate
- or (2) 100 c.c. of water  
100 grams of hard gelatine  
20—25 grams of magnesia.

Generally, instead of sodium carbonate or magnesia, the equivalent proportion of another of the additions named above, may be used. A. G. Bloxam, for the Neue Photographische Aktien Gesellschaft, 27, Siemens Strasse, Steglitz, Berlin.

Complete specification open to public inspection before acceptance under the Patents Act, 1901.

**PICTURE ATTACHMENTS.**—No. 16,923. Phillips.

## CATALOGUES AND TRADE NOTICES.

**MESSRS. HOUGHTONS, LTD.**, 88-89, High Holborn, London, W.C., have produced a useful booklet entitled "Some Hints on Enlarging," and bearing out its title. The booklet also lists the many-enlarging accessories supplied by Messrs. Houghtons.

The large list of the subjects obtainable as cinematograph films which reaches us from the Charles Urban Trading Company, 48, Rupert Street, London, W., is, after all, only a supplement to previous lists, yet it runs to 200 pages, and illustrates by excellent half-tones almost every one of the films. The Urban productions are familiar to visitors to the Alhambra, where "Urbanora" is a regular and popular item in the programme, and the list should be valued by all who are interested in public or private cinematographic entertainment.

## Commercial & Legal Intelligence.

**A "STICKYBACK" Dispute.**—Last week, before a Dublin magistrate, Mr. John Arnall, photographer, Camden Street, summoned Mr. Henry Roe McMahon, Aungier Street, for the alleged unlawful detention of fifty photographs and one dozen mounts. Mr. James W. Davis prosecuted, and Mr. McMahon defended. Mr. Davis said that the case was a row between two stickyback photographers. Complainant went into the witness box. He stated that he had been a photographer in Dublin for six or seven years. He said he carried on an extensive business. Defendant was once in his employment, and had charge of a small studio. Defendant remained with him as an assistant until September of this year. After leaving him the defendant opened a shop of his own in Aungier Street. Outside defendant's shop there were three photograph frames, and witness discovered that those frames contained a number of photographs which had been taken in complainant's studio, and the paper and negatives had been his property. It was stated for the defence that the photographs displayed by the defendant were given to him as presents by friends. Defendant gave evidence in support of this. He opened a studio in Aungier Street about three weeks after he left Mr. Arnall. He never took any of Mr. Arnall's property. All the photographs exhibited by him were his own property, and those which had been taken at Mr. Arnall's were given to him by friends. Several witnesses were called in support of this statement. The summons was ultimately withdrawn on the defendant undertaking that he would not exhibit in future on his premises any photographs taken at Mr. Arnall's studio.

**THE Ilford Dividend.**—The report for the year ended October 31 last states that, after making allowance for depreciation and provision for doubtful debts, the net profit for the year's trading is £28,419. This amount, with £1,258 brought forward from last year, gives £29,677 for appropriation. The directors have paid an interim dividend on the ordinary share capital for the half-year ended April 30, 1906, at the rate of 6 per cent. per annum, absorbing £5,700, and for the same period they have paid the dividend on the 6 per cent. preference shares, amounting to £5,700. Since then the second dividend on the 6 per cent. preference shares has been paid. From the balance, £12,577, the directors recommend that £4,000 be written off goodwill, processes, etc., and that a dividend be paid on the ordinary share capital for the half-year ended October 31, 1906, at the rate of 6 per cent. per annum, making with the above interim dividend, 6 per cent. for the year. This will absorb £9,700, leaving £2,877 to be carried forward. The sales of the company's products have shown a satisfactory increase during the past twelve months, the output being considerably larger than in any previous year of the company's existence.

## NEW COMPANIES.

**HARVEY, BARTON, AND SON.**—£5,000 (£1) (3,500 preference). To take over the business of photographers, art publishers, etc., carried on by W. H. Barton and W. H. Barton, jun., at Lower Church Lane, St. Michael's, Bristol, as Harvey, Barton, and Son. No initial public issue. First directors (not less than three nor more than five): W. H. Barton, W. H. Barton, jun., L. W. L. Thomas, and J. H. Watling. Remuneration, £100 per annum, divisible.

## ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held November 27, Mr. J. Sterry in the chair. Mr. Thomas Manly lectured upon his new process, "ozobrome," and the large attendance showed the interest taken in the process. The method demonstrated was that styled the second method in our description of the process published in our issue of October 5, and the details were so nearly the same that we need not recapitulate all of them. Mr. Manly secures a "safe edge" on his pigment plaster by the simple expedient of using a plaster that is rather larger than the bromide print to which it is squeegeed. He demonstrated the application of the process to both bromide postcards and prints. In the case of the former he recommended bringing the postcard and plaster into contact in the way described in our article on page 786, but in the case of prints he laid the bromide print of a slab and squeegeed the plaster over it. After squeegeeing the print the plaster is placed between two pieces of blotting paper and pressed between two sheets of plate glass. He recommended fifteen minutes as the proper time of contact, and explained that too long contact produced a condition akin to over-exposure, and rendered the subsequent development slower.

Mr. Manly strongly impressed his audience with the desirability of hardening the bromide print with formaline or chrome alum, expressing a preference for the latter on the ground that the effect of formaline tended to disappear in the presence of the "pigmenting solution" in which the pigment tissue is soaked.

Incidentally, it appeared that Mr. Manly has not yet found a way of dealing satisfactorily with sulphide-toned prints, and is very desirous of arriving at one. The results produced at the demonstration were all most successful, and will be left at the R.P.S., so that they can be examined and compared with the originals when dry. In the wet state the "ozobromes" show images in high relief, and the swollen gelatine naturally detracts somewhat from the apparent faithfulness of the copy. It appears that bromide prints on very rough paper are not quite so easy to deal with as those on paper of ordinary surface. Mr. Manly attributes the trouble, not to the roughness, but to the softness of the gelatine used in such papers, and hopes to surmount the difficulty with a suitable hardening bath. Asked as to the number of times the process could be repeated with the same bromide print, Mr. Manly seemed to consider that the number was unlimited if only the paper would hold out. Occasionally a poor quality of paper will disintegrate after about a dozen applications.

Mr. Sterry stated that a feature of the process that appealed to him strongly was the fine quality of the prints obtained. A bromide at its best was unsatisfactory compared with a carbon print, and the "ozobromes" had the good qualities of ordinary carbon prints. Mr. Manly previously had explained that a good bromide print was an essential requirement, as the "ozobrome" would repeat more or less the faults of the original.

WEST LONDON PHOTOGRAPHIC SOCIETY.—At the meeting held on Friday, November 23, 1906, Mr. J. Brown, vice-president, gave a demonstration on "Home Sensitised Papers." This process, which is very similar to P.O.P., appeals especially to those who like to do everything themselves. The only drawback, however, is that a good light is required for printing. The working instructions are as follows:—A piece of good paper, free from hypo., such as Whatman's, is first sized in a solution of starch, arrowroot, or gelatine, and then salted in a solution of common table salt, 5 grains to the ounce of water, or, if preferred, these two operations can be performed together. The paper is now ready for sensitising, which is done by applying a solution of 60 grains nitrate of silver, 15 grains citric acid to 1 oz. of water, to the paper by means of a mop brush, taking care to coat the paper evenly, and to avoid all air bubbles. When dry, which should be done quickly, it is re-coated in the same manner. Care should be taken to avoid using a brush with a wire round it, or pins, which, if allowed to come in contact with nitrate of silver, would cause a nasty stain. If the only brush to hand is an ordinary mop brush, the difficulty may be got over by covering the wire with sealing wax, and this will be found quite effective. The next stage is the printing. This should be very deeply done, until hardly any detail can be seen, and the print well washed before toning. At this stage there is a choice of three methods of procedure:—

1. The print may be fixed only, which gives a good sepia tone.  
2. It may be toned in gold chloride 1 grain to 15 oz. of water.  
3. The deeper the print is toned in this bath the deeper will be the resulting print after platinum toning.

4. It may be toned first with gold, then with platinum, which produces the most characteristic tone of this process—a fine blue-black.

The platinum bath is made as follows:—Dissolve 5 grains of metallic acid in 2 dms. of water, and add  $2\frac{1}{2}$  grains of common salt. When the precipitate has subsided pour off the clear solution and make up to 1 oz. with water. To this add 5 to 10 drops of a 15 grain to the oz. solution of chloroplatinite of potassium. After all the toning operations the prints must be carefully washed, as the gold bath is alkaline and the platinum bath acid. After the platinum bath Mr. Brown strongly recommended placing the prints in a solution of carbonate of soda to remove all traces of the acid before fixing.

The prints should be fixed in a 10 per cent. solution of hyposulphite of soda for twelve minutes.

The lecturer laid great stress on the necessity for thorough washing and deeply printing, as, in his opinion, most of the failures in this process were due to these causes rather than to improper washing. But he also advised that the prints should be washed several changes of water rather than a prolonged soaking for a long time.

The most suitable negative for this process was a dense negative of the type known as the carbon negative.

The Secretary then passed round some excellent examples of prints on Mattos paper lent by that company, and explained that Mattos was very similar to the paper Mr. Brown had used, except that it was supplied ready sized and sensitised, thus saving the trouble of these operations.

**CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.**—At a meeting held Wednesday, November 21, Dr. C. E. Kenneth Mees, F.R.S., read a most interesting paper on "The Theory of Photographic Processes." The paper dealt particularly with instruments used for measurements and the degrees of accuracy obtained; also the theory of development, and was very much appreciated, dealing, as it did, with the more scientific side of photography.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—At the meeting, November 22, 1906, Mr. W. Thomas being in the chair, Mr. A. J. Bull lectured upon "Bathed Plates and Ortho-work Up to Date." He was, he said, only going to attack the old problem, namely, the rendering in monochrome things that were in colour, and the only improvement in this class of work since he last visited the Association was the introduction of new dyes, the chief of which were, perhaps, pinacyanol, which was a very good sensitiser for the blue, and had in his own work brought the exposure down from one hour at  $f/16$  to one minute at  $f/64$ , these comparative exposures having been made upon the best panchromatic plate obtained and plates bathed in the new dye. Bathing the plates was extremely simple, the drying of them giving the most trouble. A clean working plate should be selected, a large dish taken, and plates placed over some three-quarters of its bottom. The dish was then gently tilted, so that the empty end was the lower, and the dye in use was poured in at the spare end. Upon tipping the dish the other way the plates would be well covered at one sweep, and at this point the light should be shut off, and the bathing finished in extreme darkness. After three minutes in the solution the plates were put into another dish and washed in running water for from three to five minutes, and then with a ball of cotton wool surfaces were wiped and the plates dried in a drying cupboard. The trouble was to dry quickly, and he found that a large box with a tray of quick-drying material in the bottom, heated from underneath, was very adaptable for the small worker. Drying should not take more than three hours; longer had a tendency to produce fog. The dyes used, pinacyanol and pinaverdol, were expensive to buy, but cheap to use, and lasted a very long way. The stock solution was made 1 in 1,000 in alcohol, and for use this was diluted to fifty times its volume in distilled water. Pinacyanol gave sensitiveness to red only, whilst pinaverdol was used for the greens and part of the red. By mixing the two dyes it was possible to make a mixture that was panchromatic, but even then the blue would predominate to some extent, and a light filter was needed, but this need not be dense

in colour. A series of comparison slides were shown by Mr. Bull, as were also a series of spectrum slides upon various plates. Mr. Freshwater asked how long bathed plates would keep, and Mr. Bull said that one for which pinachrome was used was good after eleven months, but he had not tested the newer dyes. Mr. Teape asked why would not the use of a fast plate instead of the slow one used give greater speed. Mr. Bull replied that a certain sensitiveness was obtainable upon a slow plate, but a proportionate increase was not obtainable when using the faster plates. A vote of thanks to Mr. Bull, proposed by Mr. Rapson, seconded by Mr. Teape, brought the evening to a close.

**CROYDON CAMERA CLUB.**—On Wednesday, the 21st inst., Mr. A. E. Salt dealt with some elementary branches of photographic optics, including the Gauss theory, aperture, the constancy and inconstancy of lenses, and focal length, a modified form of Day's apparatus for determining the nodal points and focal length being shown, and its principles explained. Nearly every anastigmat of note was also considered, and illustrated by diagrammatic and other lantern slides. Various practical "tips" and an explanation of the method adopted by Mr. Welborne Piper in the construction of his medalled and extremely ingenious exhibit of lens aberrations at the R.P.S. exhibition, closed a solid two hours' talk. The evening terminated with a decided difference of opinion between the lecturer and Dr. C. E. Kenneth Mees as to the possibility of being able to measure the loss of light due to reflecting surfaces in a separated lens system.

WE congratulate Messrs. C. E. K. Mees and S. E. Sheppard on being granted the Doctorate of Science of the University of London for their researches in photo-chemistry. Dr. Mees, as our readers may know, is a director of Messrs. Wratten and Wainwright, and Dr. Sheppard is at present working at Marburg, Germany, under Professor Schaum.

**MESSRS. JOHN J. GRIFFIN AND SONS, LTD.,** Kingsway, W.C., send us samples of sensitised postcards bearing Christmas designs. The cards are issued as P.O.P., Bromide, and Goldora, and the designs are certainly above the average. Messrs. Griffin are also giving away with each packet of portrait Velox postcards, until Christmas, a negative design, with Christmas greeting and masks, which permits the combination printing of the photograph and the motto on the back of the card. Price, including negative and mask, per packet of twelve, 1s.

**AN ENLARGER'S BANKRUPTCY.**—An application was made for the discharge of Alfred Margand, trading as The Crown Art Company, photographic enlarger, 115, Seven Sisters Road, Holloway, N., at the London Bankruptcy Court, on November 23, before Mr. Registrar Brougham. Mr. G. W. Chapman, who attended as official receiver, reported that the debtor filed his own petition on July 20. The statement of affairs showed liabilities expected to rank against the estate for dividend amounting to £637 3s. 4d., and the assets were estimated to produce £2, but this amount was exceeded by the claim for rent. The proofs lodged amounted to £340, and the unproved debts brought up the total liabilities to £637. A sum of £1 10s. 3d. had been realised in respect of the estate. The bankrupt was of French nationality, and after being in America for some years he came to England in 1901 and commenced business on his own account, but two years afterwards he abandoned the business. He had lost £100 through an unsuccessful action for libel brought against another person. He was also liable under judgments obtained against him early in 1902 for about £600 damages in actions for libel and malicious prosecution brought against him by two canvassers in his employment whom he had charged with embezzlement. He then went to Aberdeen, where he commenced business as a photographic enlarger in partnership with another person. The partnership, however, only lasted about six months, and since then he had carried on business alone under the name of The Crown Art Company, at Dundee and at Yarmouth. Since October, 1905, he had only carried on business from his private address at 115, Seven Sisters Road, Holloway. The books of account kept by the debtor were altogether insufficient for the business he carried on. The cash book, which was never properly kept, ceased altogether in January, 1905. The discharge was suspended for the minimum period of two years.

## Correspondence.

- \* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### A PHOTO-MECHANICAL INVENTOR IN DISTRESS.

To the Editors.

Gentlemen,—I wish to call the attention of your readers to what seems to me to be a deserving and a "helpable" case.

There is at the present time in an institution for the relief of the destitute in this town a Hungarian who, almost entirely through misfortune, got into very low water. The man has given satisfaction to, and holds references from, the following firms in the capacity of printer, retoucher, and operator:—I. Weissbach, Vienna; M. Balde, Salzburg; Joseph Albert, Munich; Wurtle and Spinheim, Salzburg; Muller, Munich; W. Bailey, late Chandos Street, and other firms in London.

He was "mainly engaged in photo-mechanical patents, i.e., automatic or self-acting machines."

What this man wants is work, and I believe that he would be found industrious and intelligent. I do not want to have donations of money sent to me on behalf of the case, as the one and only way of helping the man *permanently* is by giving him a situation. I shall be happy to answer any further inquiries about him, and it would be as well if any firm or individual who thought of employing him would write to me first.

Trusting that you may be willing to insert this letter in your paper.—I am, yours, etc.,

R. S. MEDICOTT.

The Vicarage, Portsmouth,

November 24, 1906.

### CANVASSERS: THEIR METHODS AND HOW TO FIGHT THEM.

To the Editors.

Gentlemen,—The canvassing frauds perpetrated up and down the country are now receiving many severe blows. Photographers of sound business principles should now rise *en masse* and fight it to the bitter end. The ball is now rolling, and in no case should it be stopped rolling until the frauds are exterminated. It means the uplifting of photography, better business methods, better relations between master and man, sound satisfaction to the public generally, and, above all, the uplifting of the assistants, who are struggling on with hopes of bettering their positions, but are certainly not making headway to that exalted position they would like to place their profession in. Every master, every assistant, both male and female, knows the enormous damage done to the trade by the methods of these low types of men and women, who are simply playing with photography to their hearts' content, without the slightest opposition from the profession generally, barring one or two who seem to be taking up the fight single-handed, and are to be placed amongst those who have really their profession at heart. One is really astounded to think the present-day public can so easily be gulled by these slippery-tongued canvassing fiends. People would be more astounded if they took the trouble to make a house-to-house visit and listen for themselves to the lies told by these swindling canvassers, as explained by the householders themselves.

As a photographer, I have no need to trouble about these canvassing men and women, as my clientele would never dream of allowing these men to gain a foothold, as they have been too well drilled by me in their different methods, and it is wonderful what a photographer can do single-handed to prevent these frauds continuing. After being asleep for some time, I suddenly woke up to the fact that I could fight these frauds without going to the police myself for aid. One golden opportunity gave itself to me in the shape of these men using our name to gain business by, and this

one opportunity gave me the opening to stamp out the curse in my own district.

The methods I use are the following:—In the case where a name was used for the swindling method I simply rushed to the printer's, had 3,000 circulars printed, and sent them from house to house. We explained that we were in no way connected with these men, and this gave us the opportunity to explain on other points the methods of the double gangs that travel together. The circular was extremely effective; hundreds questioned me on the things, and, above all, the local papers took it up red hot, and they put the town in such a state that the doors are simply slammed on their faces now, should any of these men and women turn up. To show how effective it was, even one of my own profession called on me personally, and thanked me for the good done, as he said that he had been able to go one step better without the desperate trouble of canvassers on his brain. The next method I use is to have a large printed card in the reception room, warning people against these methods, with explanatory remarks on the different processes and the value of frames accordingly, and one is surprised to hear one's sinner remark: "I should not have thought we could be had so easily." With these fighting methods there are numerous opportunities to explain to the people when one is questioned on the subject.

U. DOWSE.

Romsey, Hants.

### A POSTCARD CONCESSION.

To the Editors.

Gentlemen,—Doubtless you are aware that the Postmaster-General issued a new regulation, which came into operation on November 1, providing that no postcard must be less than 4 in. in length and 2½ in. in width. A considerable trade in sensitised postcards in the size 3½ by 2½ in. has been done, and we wrote to the Secretary of the General Post Office, pointing out the inconvenience and loss that would arise if this regulation came into force without some due notice, and we are pleased to report that to-day we have received the following reply:—

"In reply to your letter of October 31, I am directed to state that in view of the inconvenience which might in some cases be occasioned to dealers in postcards by the immediate enforcement of the new minimum limit of size, the Postmaster-General has decided that until the end of April, 1907, cards which are not smaller than the old minimum size of 3½ in. by 2½ in. are to be allowed to pass without challenge, provided that in other respects they conform to the present postcard regulations."

We are, yours faithfully

ELLIOTT AND SONS, LTD.

THEIR Majesties the King and Queen of Norway, his Royal Highness the Crown Prince Olaf of Norway, and her Royal Highness the Princess Victoria honoured Messrs. W. and D. Downey with sittings for their photographs last week.

PHOTOGRAPHIC Trade in South Africa.—A somewhat unusually optimistic view of trade in South Africa is expressed in the "British and South African Export Gazette." The author of it is Mr. J. H. D'woodie, President of the Transvaal Board of Pharmacy, who, in reference to the photographic side of the chemist's business, says:—"With regard to the trade in photographic materials, this is a very big line with chemists in all colonial centres, for the amateur photographer is a great power in the land. Everybody in South Africa possesses a camera at one time or another, and there are plenty of temptations for using it. The business is confined to reliable all-round goods, and there is no demand for such items as special lenses, etc."

MR. H. W. LEWIS, of the St. James's Colour Studio, was commanded to appear last Saturday at Buckingham Palace to photograph little Prince Olaf, Crown Prince of Norway, and obtained some very successful results.

GRANTHAM Industrial and Fine Art Exhibition.—The twentieth annual exhibition is to be opened at Grantham on January 30. From the schedule just published, we find there are 110 classes for competition, including oil and water-colour painting, photography, needlework, repoussé work, etc., open to all England. The schedules can be obtained of Mr. Geo. Jackson, Grantham.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- A. Walker, 58, Queen Street, Maidenhead, Berks. Photograph (combination) containing five different views of Maidenhead, with floral decorations and Crest.
- J. R. Browning, 11, Bedford Circus, Exeter, Devon. Photograph of H. J. Edwards, Doctor of Music. And two photographs of D. J. Wood, Doctor of Music.
- W. A. Sawyer, "Westfield," Dover Road, Walmer, Kent. Two photographs. Brass band of the R.M.L.I. Depot, Walmer, and the string band.
- W. T. Carter, 43, Drake Street, Rochdale. Photograph of Rochdale Town Council and Officials, 1906.
- J. Terras, Lawhead View, Markinch, N.B. Three photographs entitled, "At the Fountain," "News of Battle," and "The Postman."
- C. W. Clarke, 57, Richmond Place, Beacon Hill, Bath. Photograph (combination) of an original poem entitled "Mister Skimy-tail," with six birds and six snails alternating round same, forming a border.
- W. J. Moffett, 53, Bridge Street, Portadown. Photograph of Mr. Wm. Moore, K.C., M.P., addressing Constituents in Portadown with his coat off.
- W. A. Culshaw, 119, High Street West, Sunderland. Photograph (combination) of a placed group of eleven Sunderland League Players.

- S. D.—There is no better method than stripping from plate glass, polished with French chalk (which must be all dusted off again). The prints should be alummum.

**COPYRIGHT.**—I have a set of copyright photographs selling as post-cards, showing various attitudes of drill by boy's brigade. Some local person has sent one of the cards, unknown to me, up to —, and it has been reproduced in their paper for November. I wrote them about the matter, and a card was sent, in reply, that they would investigate. A later letter says the following: "Sir,—We have now made further enquiries in the matter of photograph reproduced in our last issue, and find that same was taken in a ground which had been engaged by the people concerned for their own exclusive use for that day. Under the circumstances, as you had not obtained the necessary permission, we do not see how you can justify your claims to copyright." How do I stand over the matter? Is that a safe plea on their behalf? I took the photographs after I had paid for admission, and also the grounds are a public park, but admission was charged for that day. By their letter, copyright in these photographs belongs to the committee. I take it that I can claim upon them for reproduction in their magazine, as copyright is entirely my own, and have claimed from them a fee as well as an apology through the local Press.—MAGAZINE.

Providing that you registered the copyright before the reproduction complained of took place, you have a clear case for action. The fact that the grounds were exclusively used by other persons has no bearing on the validity or otherwise of your copyright in the photographs then taken.

**GOODWILL.**—You would greatly oblige if you would inform me what you consider is the usual custom for arriving at the value of "goodwill" in a photographic business—that is to say, the basis upon which reckoning should be made? I assume you will deal with this in your "Correspondence Column," and under the heading "Goodwill."

Your question scarcely comes within our province to answer—

it is such a purely business matter. However, in our volume for 1902, p. 585, is a long and exhaustive article on the subject. This, no doubt, will give you all the information you desire, whether you are purchasing or selling a business. You will also find much useful information in the book, "How to Buy a Business," recently reviewed in our columns.

**ANXIOUS.**—With a lens of sufficiently large diameter and fitted with two diaphragms, or with the "transmitter" sold by Theodore Brown, of Bournemouth.

**DISPUTED CONTRACT.**—A reply to the following in your next issue will oblige: A year ago a representative of the — Advertising Company called and induced me to advertise in a case affixed to the wall in the market place. The engagement, as far as I understood at that time, was for a year for 35s., payable in advance. They now say the contract was for two years, but I am quite sure nothing was said about a two years' contract at the time, and I cannot understand my signing a two years' contract without knowing it. I am enclosing the letters just received from them, and should thank you for your opinion. Could I demand to see the original contract?—GLOBE.

We cannot understand anyone signing such a contract without noticing it was for two years—that is, if the form is the same as the copy that has been sent you, for in that "two years" is printed in bold type. We should advise you to go to the office of the company and demand to see the original contract, and if the people cannot or will not show it let them sue you in the county court. There they will have to produce it, or they will lose their case. If you see the original, and it is the same as the copy, you will, of course, have to abide by the contract. Should you find that the original does not agree with the copy, we should advise you to send the particulars to the secretary of the Professional Photographers' Association—that is, if you are a member of that useful body. The correspondence has been returned to you as requested.

**H. J. LEWIS.**—Better take out provisional protection (cost, £1) before showing the lamp to anybody.

**SWING LENS.**—The arrangement seems perfectly satisfactory. We should advise you to approach one or two camera-makers with it. If it is adopted, you can complete the patent—if not, you can save your money. There are, of course, several patented methods for obtaining the same end.

**BROMIDES.**—What is the quickest developing process for turning out quantities of postcards? I have been using rodinal, but find it takes a whole evening to properly turn out a dozen. I have been used to P.O.P. work. ENQUIRER.

The quickest method would certainly be to find first the correct exposure for the negative, then expose, say, three or four dozen, and make up a good quantity of developer, either rodinal or metol-hydroquinone; then immerse about a dozen cards in the developer one after the other, and develop till sufficient depth is obtained. Throw the cards, as developed, into a good-sized tank of running water, leave for a few minutes, and immerse a second dozen cards in the developer. Whilst these are developing remove the cards from the tank into the fixing-bath. Proceeding in this way it is possible to turn out a very fair number of cards in the evening. Great care must be taken, of course, not to use the developer too long, or it gets too slow; also to avoid any transference of the hypo into the developer; but if one hand is kept for developing and the other for the fixing there should be no trouble from this. Naturally an exposing machine would considerably facilitate matters.

**COPYRIGHT INFRINGEMENT IN SOUTH AFRICA.**—It has just come to my notice that one of my Naval comical pictures (which are registered and copyrighted) has been copied by a photographer, an Englishman, in Simons Town, S. Africa, and that he has been selling same for some time now. I shall be glad if you can tell me if I have any remedy in stopping him selling (he being in South Africa), and the best means of getting at him. I may say that I have a similar case at Hong Kong, but it is a Chinaman.—NAVAL MOUNTED HORSE.

Your copyrights are valid in South Africa, and you can proceed against the maker and vendor of the cards. You had

better consult a solicitor, to whose notice it may be well to draw the *résumé* of the copyright law in the "Almanac," 1906.

**BURDETT MASON (France).**—All depends on focal length of your eyepiece. The length of tube, or separation between objective and ocular, is about equal to the difference between the focal lengths of the two lenses. Thus with a six inch ocular the length would be about 18 inches. For photographic work, if both lenses are used, the tube length will have to be greater. The whole telescope will then be similar to a telephoto lens.

**PARTNERSHIP.**—Will you kindly reply to the following question? A and B were partners as photographers, picture framers, etc., the studio being about 200 yards away from the shop. They have dissolved partnership, and A paid B out. C buys the studio from A, with the goodwill, cameras, and all negatives since the commencement. B opens another shop and studio, about 300 yards from studio now belonging to C, and is showing specimens from negatives belonging to C, the said negatives having been taken away before the dissolving without permission of A, and the negatives being orders in the book of A and B. Now C had some orders for photographs, and could not find the negatives, the said B having taken those negatives away, and is showing specimens from those very negatives, as well as from the others he has taken away. Has C any claim for damages against B? If so, which is the best way to proceed?—A. W.

This is a question for a solicitor to deal with, after seeing the deed of partnership and the conditions under which it was dissolved. It rather seems to us, from the facts stated, that C can take no action against B, as he had no dealings with him. His action, we imagine, would be against A for not handing over the whole of the negatives. A might have cause for action against B for taking away the partnership negatives. But, as we have just said, the question is one for a solicitor's opinion, after he has learned all the facts.

**STUDIO QUERIES.**—I am thinking of opening a branch business, and have some premises offered me, but at present there is no studio; the only available room is on the first floor, and is 16ft. x 10ft., with only one window at the end, but think I can get permission to knock out the end and extend it by about 5½ft., on girders, over a pathway at back of premises. I fear it cannot be extended more than this, as it would then project over a graveyard, and no doubt the authorities would object. The extension I propose to be glass both sides, also roof, so that I could light from either side as desired. (1) I should be much obliged if you would inform me if you think I can get sufficient light from this amount of glass to do good work. (2) Also what space should be unglazed at the end (top and sides) for the backgrounds? (3) What would be the most suitable focus lens to use for cabinet portraits in studio of this length (21½ft. with proposed extension)?—NORMAN.

(1 and 2) It seems to us that even with the extension you will have a very unsuitable studio for doing good work in, inasmuch as all the light you will have will be immediately over and at the sides of the sitter. It will be necessary to have some portion above, and at the sides, of the sitter opaque, and if this is only, say, 3ft. or 3ft. 6in., you will only have about a couple of feet of light to work with. If you use the light from the extension as a side light, you would not have sufficient length for the camera. The best plan is to put a side light in the room, if possible. (3) A portrait lens of about 10¼in. or 11in. focus.

**WET COLLODION TROUBLE.**—I have made a silver bath for wet collodion work, and it has worked clean and well for the first few days. Now a fog appears during development (which after wiping off and redeveloping I get the same desired result), but, of course, risking scratching film in doing so. Can you tell me how to rectify this, as I keep bath on the acid side. I use every care as to filtering, cleanliness, etc.—WET PLATE.

As you say, the fog is only on the surface of the film, and can be wiped off, we should suspect that it is the developer, and not the bath, that is at fault. Try the addition of more acetic

acid to it, and see that the vessel from which you pour it to the plate is perfectly clean. If that does not remedy trouble add a drop or two of nitric acid to the silver bath.

**J. G.**—If you have made the cards you can sue the man for the whole amount, or for whatever part of the commission you have done.

**F. M. (Penge).**—You can get a higher gloss by stripping from conditioned glass, but we think you will find the use of plain plate glass (polished with French chalk) in place of the ferrotype plate give you sufficient improvement.

**ARTIST.**—Any large draper will supply a canvas to take a distemper coating. As to rollers, we doubt if the trade houses would supply you, except in very large quantities. Better try O. Sichel & Co., 52, Bunhill Row, E.C.

**REASON AND OTHERS.**—In our next.

**CANVASSING FRAUDS.**—The "Llangollen Advertiser" quotes a portion of our recent articles on the free enlargement frauds by which residents in its district have been defrauded. Our contemporaries point out that "these men are not travelling the country at certain amount of expense, to give goods away; and all who get their proposals a moment's serious reflection will recognise at once that they bear upon them the impress of fraud. In these hard, dry, matter-of-fact business days, reputable firms do not do business upon such lines; and our advice to readers is, when proposals are made to them to participate in back-door transactions of this nature, to clear their pockets, open the kennel door, and let the house-dog do its worst."

**AMATEUR PHOTOGRAPHY IN CEYLON.**—A society has been formed in Ceylon as the result of a meeting convened by Dr. Andreas Neill of the Victoria Memorial Eye Hospital, Colombo, Ceylon. At the meeting a number of influential people were present, and it was announced that the society started with a membership of seven. Dr. Neill was elected secretary, and Mr. J. H. de Sarum president.

**HERR F. SCHROEDER** recently described, before the Breslau Photographen-Verein, his flashlight apparatus, one of the chief features in which was a large banner, one side of which was dark, which turned towards the lens, protected it from any light from the flash itself. He stated that with two of his flash-lamps, with lens working at *f*/32 he was able to obtain full exposure with 60 grains of powder in each lamp, the plate being a 20 by 16 cm. The use of the dark banner enabled the lamp to be well in front of the lens.

A postcard frame, entitled the "Wilco," has been placed on the market by Mr. Chad Hodgson, 5, Wade Street, Leeds. The frame consists of two parts, one of which laid on the other forms the complete frame. The negative is placed between the two portions, and each postcard is thus given a white margin without the aid of a mask. The frame lends itself to the making of a number of identical prints. Its price is 2s. 6d., post free, the maker offering to send it on approval.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The first portrait taken by Daguerre is stated by the nephew of the sitter to have been Mr. Andrew Shanks, a well-known British engineer of the last generation. (P. 977.)

Dr. W. Scheffer, of Berlin, contributes the results of a micro-optical examination of negatives reduced with the ferricyanide and persulphate reducers. The photo-micrographs show how the former penetrates slowly and dissolves quickly, whilst the persulphate penetrates quickly and dissolves slowly. (P. 964.)

Following on the experiments of Professor Korn on electrical long-distance transmission of photographs, a French engineer, M. E. Jehn, of Nancy, has announced his discovery of a method of photographing at a distance or of even cinematographing by electrical connection. (P. 972.)

Dr. W. J. Russell, F.R.S., has examined the action of many plants and the seeds of plants on photographic plates in the dark, the results of which favour the hypothesis that the active agent concerned is hydrogen peroxide. (P. 966.)

The Canvassing Frauds.—A gang in Sheffield which absconded suddenly left behind them a large number of photographs and enlargements, the re-distribution of which has been undertaken by the police. (P. 972.)

The reception-room and how it should be furnished and decorated. (P. 963.)

A movement is reported in Austria in favour of the abolition of peeping studios on Sunday. (P. 962.)

Major Puyo hopes to apply the ozobrome process to oil printing, as introduced by Mr. G. E. H. Rawlins. (P. 969.)

## EX CATHEDRA.

**"Gum-Bichloride."** A particularly choice gem of the photographic ignorance which we are accustomed to find blazing in the lay Press occurs in an American journal, "The Great Round World." The following is its illuminating description of gum printing:—"The newest process is the bichloride of gum, discovered and made practical by a man named Demachy, the leader of pictorial photography in France. The process is simple, consisting of a basis of bichloride of gum-arabic and bichloride of potash, to which can be added any shade of colouring matter." Not content with this howler, the writer has interviewed Mr. Alfred Stieglitz in New York. His version of the conversation with Mr. Stieglitz on the roof of the Camera Club is distinctly good reading. The Director of the Photo-Secession is reported to have described his entrance into pictorial photography as due to his having "gradually switched over to the art side." In dispraise of medals, Mr. Stieglitz is made to affirm: "We have ruled out all that sort of junk out of expositions." The hasty journalist has many things to answer for, but it is rarely that he manages to crowd photographic errors quite so thickly on one another as in the article before us.

\* \* \*

**Free Portrait Canvassers.** The recent publicity given to the canvassing frauds by the "Perth Constitution" had the happy result of effectually driving the canvassers from the district, and, as we reported, in our last issue, the same result was achieved in Romsey, Hants, through the active measures taken by a photographer there, Mr. U. Doust, supported by the local Press. The latest intelligence to reach us of the same species of fraud, and probably of the identical gang who are working it, is from Helensburgh. Their methods have come in for some caustic comments from the "Helensburgh and Gareloch Times." In Sheffield, as reported on another page, the gang has fled from the town, leaving the photographs and the "free enlargements" made from them to be dealt with by the police. We should like to express the hope that the larger papers throughout the kingdom will publish a plain exposure of this bane to photographers and the public alike.

\* \* \*

**Home Preparation of Papers.** Some weeks back, it will be remembered, we made a few comments on the apparent neglect of photographic technics by photographic societies generally. But these must not be applied to the energetic West London Society, whose programme includes a number of papers of a really practical

ture. At its last meeting Mr. J. Brown gave a demonstration on "Home Sensitised Papers," a very interesting, as well as useful, subject. There was a time when every photographer—professional or amateur—had perforce to prepare his own paper, as then there were no ready sensitised papers in the market. The methods of preparing them in those days were in some respects different from those now adopted, which are in some instances not so satisfactory as the older ones. In salting the paper, for example, it was usual to float it on the salting solution. By this means the printed image was retained more on the surface of the paper than if it were immersed; consequently there was a greater transparency in the shadows when the picture was finished. In sensitising the paper it used also to be floated on the silver solution; now it is generally applied by brushing it over the paper. The old method was the simpler and was the more quickly done, and, at the same time, the sensitising was more evenly accomplished than is possible by brushing the solution on to the paper. Moreover, there was no risk of disturbing the fibre of the paper. At the present time, when possibly only a few sheets of the paper are required, it would be inconvenient to many to make up sufficient silver solution to float, say, 15 by 12 sheets upon; hence the brush is used. In the olden days, when the ammonia nitrate of silver (which would keep but a short time) was used as a sensitising agent, only a small quantity of it was prepared at a time, and it was applied in this way. The salted paper was laid on two or three pieces of blotting-paper; a glass rod a little longer than the width of the paper was laid at one end. Then a little of the solution was poured along it, and the rod passed along the paper, carrying the solution before it, which was afterwards evenly distributed with the rod, if necessary. In this way a number of sheets of paper may be sensitised without a large quantity of silver solution being required. Furthermore, there is no risk of the texture of the paper being raised as there might be by brushing.

#### Brushes for Coating.

When brushes are used, camel-hair ones are those that are usually employed. These are generally mounted in tin, and any of the silver solutions coming in contact with the metal will be immediately decomposed; added to this, the brush has to be thoroughly cleansed each time after use. Also, the silver has a deleterious action on the hair. Better than camel-hair is what was known as the Buckle, or the Blanchard, brush. The former was simply a tuft of cotton wool drawn into a piece of glass tube. The most convenient way of making one is to take a large test tube and knock a hole in the bottom with a piece of wire or a penholder, then pass a piece of doubled string through it, then drawing into the open end by the loop a tuft of cotton wool. After the loose fibres of the wool have been pulled off, the brush is ready for use; and when done with the wool can be thrown away. The Blanchard brush is different, and is better suited to the purpose when large surfaces are to be dealt with. To make it, a piece of glass is taken, say, a quarter-plate, and over one end a piece of swan's-down is doubled, fluffy side outwards, and the ends secured with an indiarubber band. The swan's-down can be thrown away after use, or washed out ready for use when next required. Both these appliances, it seems to us, are preferable in all ways to the more costly camel-hair brushes. While on the subject of home-made papers, we may mention that in most modern formulæ chloride of sodium—common salt—is given as the salting medium. With the old workers it was tolerably well known that the chloride used had a marked influence on the colour of the image when printed. The chloride of sodium, the chloride of barium,

and the chloride of ammonium all gave a different colour in the printing frame, and the first-named salt was rarely employed. It was the last two that found most favour when photographers had to prepare their own papers.

#### Photographs with Apparent Relief.

The idea of producing photographs in relief is by no means a new one. Patents have from time to time been obtained for producing photographs in has relief and companies formed to exploit them, though few of them have proved of much commercial success. Most of the methods have been based upon the swelling properties of bichromated gelatine when printed from a photographic negative and obtaining a plaster of Paris cast from that. The specification of a patent, applied for in this country by an American inventor, has just been published for producing photographs which are "optically in relief, or intaglio, while they are mechanically flat." From the specification (which is abstracted on another page), the method is seen to be as follows: First, a negative of the subject is made in the ordinary way, and a transparency produced from it. These two pictures are then superimposed a short distance apart and a fresh negative then made from them by transmitted light. In lighting this compound picture an oblique light is employed so that a somewhat strong shadow is obtained from the image. This negative yields a print which has the appearance of being somewhat in relief. It may be remembered that a short time back Mr. Gordon described a method of making photographs in apparent relief by printing from a negative and transparency superimposed. The method described in this specification appears very similar. While on the subject of photo-reliefs, we may mention a curious fact that may not be known to everyone. If a photograph be made of coins or medals or plaster casts from them, illuminated by a strong sidelight so that there are good cast shadows, the designs will appear in strong relief when the picture is looked at the right way up. But if it be turned upside down the design will then appear to be in intaglio and not in relief as before. This optical illusion is, of course, simply due to the inversion of the shadows.

#### Magic Postcards.

We see from an Australian paper that a form of postcard is upon the market the origin of which, we have no doubt, is photographic. The card is purchased in a light-tight package, and on exposure to light acquires a picture which is permanent in the light. Those who have experimented with bleaching agents on bromide prints will not experience much difficulty in drawing up a formula for the preparation of such cards, a variant of which, we believe, has been patented and manufactured in Germany. According to the brief particulars which have been published, the bromides are bleached in solutions of copper salts which contain also certain proportions of alkaline chloride. The idea has been worked out, we believe, of producing a card bearing a partial picture, additions to which make their appearance on the card being kept in the light. This modification should also be possible by taking advantage of the various toning and bleaching compounds.

#### Sunday Photography Abroad.

While legislation is pending in our own Parliament on Sunday labour, it is worthy of note that a movement which appears to be of considerable magnitude is on foot in Austria among the photographic employers and their employees, the object of which is to reduce or abolish the opening of studios on the Sunday. We read in the Munich

Journal, "Photographische Kunst," that in Budweis, a town of 35,000 inhabitants and six photographic studios, all the latter have joined in closing on the Sunday, and that in Prague and Vienna the closing all day or at 4 o'clock on Sundays has been very actively taken up by both classes in photographic establishments. While we should advocate resistance to the suggested interference of the Government in making Sunday closing of businesses compulsory, we would commend these measures of conference and united action to photographers in English towns, many of whom are compelled to work seven days in the week, not because there is a great business on the Sunday, but because a competitor keeps open. This form of competition applies more especially to the cheap class of trade, but the same argument may be expended with even greater force to the half-day weekly closing, which is impossible in many towns owing to one firm standing out from an arrangement.

### THE RECEPTION ROOM.

The up-to-date photographer cannot spend too much thought on his reception room. From a business point of view it is the most important part of the establishment. It is here that the prospective sitter obtains that most important first impression, which, if it does not actually lead to the making or marring of an appointment, frequently has great bearing upon the spirit in which proofs are received. A tasteful reception room will give the sitter a reassuring idea as to the status of the business, and will lead to a more confident order. A slovenly, patchy, or even an over ornate, room will lay the germs of misgiving that will tinge all further transactions, leading, if not to dislike of proofs, to a very guarded order. Moreover, good specimens tastefully displayed tell their own story, and orders for more expensive work than that otherwise intended should result.

Nothing out of the ordinary in the way of decoration is required. Good quiet wall-covering, artistic artificial light fittings and wood-work, whilst the furniture should be solid, substantial, and good, but not in any way gaudy. When decorating a room one must remember that a certain amount of repetition has to be introduced. A very good rule is to decide on a scheme in two prevailing colours, and stick to them, introducing as little as possible of any other tint. Blue and green are a good combination, so are brown and green or brown and cream. Cream and red, too, is a splendid combination, but not satisfactory for a reception or show room, where the great necessity is that the wall-covering should be quiet, dark, and unobtrusive, so that pictures are shown off without any distractions.

When choosing wall-covering, therefore, it must not be chosen for its own inherent beauty, but for its value as background for pictures. It will scarcely be necessary to add that papers with very small indefinite patterns in itself colour or quite plain papers or fabrics are the only suitable ones.

When selecting furniture, go in for straight lines and plain square features. Turning usually looks cheap. Avoid carving unless you can afford real antique. Carpets, of course, vary; the very dear Donegal carpets at £2 2s. a square yard are unapproachable, though the Goblin art squares are equally artistic, and about five shillings per square yard. Art canvas cannot be beaten as an artistic wall-covering, and, if broken into panels with a simple moulding, the result is rich and impressive. A good plain paper, however, will look well if a suitable frieze is chosen, and the furniture, etc., satisfactorily harmonises. We

should advise the prospective purchaser of art canvas to get plenty of patterns, for the material from different firms varies greatly in price.

A good table should be obtained for showing mounted prints, since it is very inadvisable to keep specimens scattered about; one with a shelf underneath is useful, so also is a chest of drawers with glass top and receptacle for miniatures, coloured work, or any special goods which it is desirable to give an added suggestion of value. The drawers should be shallow, say three inches, and, if provided with movable trays to hold specimens, are very useful.

The mantelpiece and overmantel may be made into very valuable pieces of furniture, and it would pay to have one designed by an artist with the special idea of its position in a photographic show room. A mirror should not be included, the space being more profitably and suitably occupied by panelling, against which the framed pictures will show to greater advantage. If, however, it is not desired to make a feature of this important adjunct to the room, simplicity may once more be relied on to demonstrate its pictorial value. Do not go in for the elaborate marble arrangements so popular during the Victorian era, but rather have a simple wood mantel harmonising with the furniture and tiles, agreeing in colour with the general scheme. The grate itself should not be highly polished or elaborated with ornament. The pictures to be hung on our walls should have frames that not only harmonise with the prints, but also with the walls. It will almost be unnecessary to warn the reader against gilt frames.

Above all, do not crowd the walls. A very few perfect specimens have a most pleasing, restful, and tasteful effect, quite different from the general tone conveyed by overcrowded walls, where a multitude of specimens kill one another and defeat the ends of the photographer who wants by his exhibition to convey an adequate idea of the work done. Touching on this subject one may refer again to the mistake of overcrowding tables with unframed specimens. Two or three in tasteful folders are quite sufficient to have lying loose; the others should be kept in trays easily brought forward and returned. The slovenly effect of a number of photographs lying jumbled up and necessarily dirty is very distracting and harmful. It would be just as well to classify these trays, such as men, ladies, children, heads, three-quarter, etc., for, as any one of reception-room experience knows, the prospective client has usually very definite ideas as to the position, etc., required before entering the establishment. The proprietor himself should occasionally go through the specimens and weed out the worn and old.

It is, we think, a great mistake to have a counter in the reception room, for this is much too shoppy. Facilities for writing must, however, be handy, and a neat desk of the pedestal type will not be out of place in an unobtrusive position.

The old-fashioned album has almost disappeared, though a few silvers or other cheap line kept in them very effectually transfers a client's ideas to platinotype and carbon. It is useful, however, to have a book with plain leaves and thick guards into which to place the modern paper mounts one on a page. If the prices and name of the style are appended it is often more comprehensible than voluminous explanations made by the receptionist.

HIS MAJESTY THE KING has bought from Mr. F. A. Swaine, of Southsea, a copy of his successful pictorial photograph called "Even-song." A copy of this picture is now on view at the New Zealand Exhibition, promoted by the British Government.

# MICROSCOPICAL RESEARCHES ON THE EFFECT OF THE PERSULPHATE AND FERRICYANIDE REDUCERS AS ALSO ON THE REDEVELOPING OF BLEACHED NEGATIVES WITH ALCOHOLIC DEVELOPERS.

It is a well-known fact that the ammonium persulphate reducer of Lumière produces soft, and that of Farmer (ferricyanide of potash), harsh results; i.e., the former attacks the parts of the gelatine which are rich in grain, more than those which are poor in grain. The ferricyanide works in the opposite manner.

The question in point for the experiments here described was: Is there any difference in the topographical behaviour of the two types of reducers in the gelatine film?

Fig. 1.

First, a few bromide of silver dry plates were exposed, fixed, and thoroughly washed. Then each plate was divided into three equal parts, one of which was set aside for comparison, the second was reduced in persulphate of ammonia, and the third in ferricyanide of potash. This was done in such a manner that the two reduced pieces gained the same amount of

Fig. 2.

transparency. The three films were then carefully stripped and vertical sections were made with the microtome. Figs. 1 and 2 are photo-micrographs of sections of the reduced films. Fig. 1 is reduced with ferricyanide: Fig. 2 with ammonium persulphate. It can be seen from Fig. 1 that the effect of the cyanide is distinctly limited to the upper part. Here all grains are dissolved while in the lower half they are not touched. The persulphate of ammonia, Fig. 2, has worked in quite a different

way. It has penetrated the whole film and has reduced grains in an equal proportion. The original film had the same appearance as the under half of Fig. 2. The difference in the action of the two reducers lies in the fact that the Farmer reduces the grains according to their position in the film; the nearer the grains lie to the free surface the earlier they are dissolved, and the upper have entirely disappeared before the

Fig. 3.

Fig. 4.

lower show any change. In a manner of speaking, the persulphate of ammonia works inversely. It is a matter of no difference to this reducer whether the grains lie on the surface or on the lower parts of the film near the glass. It reduces grains approximately at the same time no matter if they are located in the uppermost or lowest parts of the film.

Fig. 5.

It is to be seen from this that the Farmer reducer penetrates the film relatively slowly, and dissolves the grains relatively quickly, whilst the persulphate reducer penetrates very quickly and dissolves the grains very slowly. The relation of the time taken by the reducer to penetrate the gelatine to that taken

Fig. 6.

Fig. 7.

dissolve the grains determines the harsh or soft action of the reducer.

Figs. 3, 4, and 5 show these processes graphically. For the sake of simplicity the grains and their behaviour in the reducer are shown in circles. Fig. 3 is the film before reducing. Fig. 4 shows the reducing with ferricyanide. It must be stated that this reducer penetrates the film approximately with the same

speed, no matter whether the part of the film is rich or poor in grains. It has been seen that the ferricyanide of potash reducer has dissolved all the grains in the parts where a comparatively small number of grains is to be found; i.e., it has destroyed all details of the image in these parts, whilst the parts which are rich in grain are comparatively weakly attacked. A print

Fig. 8

from such a reduced plate would be harsher than one from the same plate before being reduced.

Fig. 5 shows the working of the persulphate reducer: in this case the parts which are richer in grain are naturally comparatively strongly attacked.

Fig. 9

Let  $L$  be the transparency of a certain part of a plate,  $U$  the opacity, and  $S$  the quantity of grains. If we reduce with persulphate in such a way that we dissolve the half of the quantity of grains equally over the whole plate the former opacity is to that now obtained as  $U : \sqrt{U}$ . Let us take, for example, a part which has the opacity 100, that is which lets through 1/100 of the incident light, and another part whose opacity is 9,

i.e., which lets through 1/9 of the incident light. After a reduction which dissolves half of the grains, the more opaque part will have the opacity of  $\sqrt{100} = 10$ , and the more transparent parts an opacity of  $\sqrt{9} = 3$ . From this it can be seen how the persulphate of ammonia makes a negative softer.

Figs. 6 and 7 show the reduction of the grains graphically. Fig. 6 shows the action of persulphate of ammonia; Fig. 7, that of ferricyanide of potash. It has been supposed that the grain is half dissolved.

There is another known process of reducing. The negative is first bleached, then again developed. Herr Hans Werkner has lately published in "Helios" a good method of redevelopment, which is specially suited for the purpose of changing harsh negatives into soft ones without loss of image in the transparent part.

The bleaching solution is made up as follows:—

Water .....	100 ccs.	.....	3½ ozs.
Potass. bichromate conc. sol..	10 ccs.	.....	170 mins.
Hydrochloric acid, conc. ....	2-3 ccs.	...	34-50 mins.

After thoroughly washing, the plate is redeveloped with

Alcohol .....	100 ccs.	.....	3½ ozs.
Pyrocatechin .....	1 gm.	.....	16½ grs.

And

Alcohol .....	100 ccs.	.....	3½ ozs.
Caustic soda .....	0.5 gm.	.....	8 grs.

Mixed in equal parts.

Figs. 8 and 9 are sections of films before and after this treatment. The hardening of the gelatine by the alcohol retards the penetration of the developer, so that it can only affect the upper parts of the gelatine. Consequently only those grains can be redeveloped which lie in the upper parts and not the lower ones, so that nothing of the image will be lost in the places poor of grain; but in the richer parts where the grain reaches deeper, comparatively much of the density is lost. This process is, in a sense, similar to a hypothetical reduction with ferricyanide of potash from the glass side.

Finally it may be stated that it is not possible, by changing the relative amount of ferricyanide and hypo in water to obtain a Farmer's reducer which works softly, similarly to persulphate of ammonia. Every test showed that the typical differences remain. Herr Doctor Lüpko-Kramer has lately published some interesting facts about the chemical constitution of negative parts rich in grains (long exposure), and those poor in grain (short exposure). The statements of Dr. Lüpko-Kramer are also entirely confirmed by microscopical research.

I intend shortly to publish some articles on this subject. It is probable that the facts detected by Dr. Lüpko-Kramer, together with the facts described in this article, explain the aforesaid differences in the working of the two reducers.

DR. W. SCHEFFER.

## ORTHOCHROMATIC WORK AND THE BATHED PLATE.

A Paper read before the London and Provincial Photographic Association.

The great superiority in colour sensitiveness of plates bathed in the newer iso-cyanine sensitisers over anything previously procurable necessitates some modification in the colour filters employed to obtain approximately correct colour rendering, where such plates are used. The increased sensitiveness to red of some of these plates, for instance, one which has been bathed in a mixture of pinachrome and pinacyanol, renders superfluous the employment of orange filters of the classes described in a previous paper, particularly one (type III.) possessing a gradual absorption throughout the spectrum. To obtain with the particular plate mentioned a good rendering

of coloured objects, one may adjust to it either a yellow filter having a somewhat abrupt absorption in the blue or one where the absorption of the blue and violet is gradual. The former type is perhaps preferable, on account of the greater transparency to the shorter wave-lengths that is obtained, and the result is less likely to be modified by any variation in the ratio of the plate. The complete absorption of the spectrum violet which this entails is without serious effect in the rendering of compound colours, for the reason that violet is a colour which practically never occurs alone in nature, all ordinary violet colours reflecting some blue and red in addition to violet.

A filter absorbing all light of shorter wave-length than 4,700 A.U. gives the requisite correction for a commercially-bathed plate sold under the name of "Panchromatic," to render subjects of all colours very correctly as regards their light and shade. This combination of filter and plate has, moreover, the very practical advantage that it is sufficiently rapid to employ in all ordinary work, the H. and D. speed being somewhere in the neighbourhood of 60. It has been used for focal plane shutter work. A liquid form of this filter may be made by using a solution of picric acid, 0.5 mgr. per c.c. in a glass cell having 1 cm. internal thickness. In view of this my previous paper may therefore be modified as follows, that is, of course, if one has regard only to the most colour sensitive of the available plates.

1. For green sensitive plates of the erythrosine type, which still predominates in numbers, one may with advantage, for landscape and some other work, employ an abrupt absorption filter, absorbing at about 4,900 A.U.

2. Secondly, where reds and oranges are colours of importance, the filter and plate described above for the correct rendering of all colours is all sufficient. This combination has been used with equal success for landscape and interior work, and also for copying in picture galleries. It does sometimes happen that strictly correct colour rendering is not desirable, chiefly in copying pictures, where an over corrected effect may be more pleasing. This is readily accomplished by employing a somewhat deeper yellow filter than the one specified above, which will lighten the reds and oranges and darken the blues. The reverse effect is obtainable by using a filter transmitting more blue light.

The filters and plates for selective colour work, where the object may be either to enhance or minimise colour contrasts, are not affected by the introduction of the bathed plate, except in that exposures under red filters may be reduced to less than one hundredth of that previously necessary.

The following are the most useful selective filters:—

1. To photograph reds and yellows as white, thereby reducing

the contrast between these colours and white and increasing contrast with greens and blues. This effect is given by a red filter and panchromatic plate.

2. Any of the green sensitive plates and a yellow filter absorbing all light beyond 5,000 A.U. will tend to reduce the contrast between yellows and greens, and white, while increasing it between violets and purples, and white.

3. The ordinary plate without any filter photographs blue and violet lighter than they appear, and renders as black a great majority of yellows, oranges, and reds; greens, too, if yellow shade may be very dark.

4. Another filter, which has proved very useful in process work where the wet collodion plate is being used in conjunction with the enclosed arcs, is one absorbing the ultra-violet, because some of the "whites" which are used in the original drawing absorb this light, and in consequence photograph darker than they should.

5. A rhodamine filter and pinacyanol bathed plate are occasionally useful to render greens as black and lighten in tone most other colours. That some colours in general give rise to greater colour contrast in photographic work than others depends upon the fact that the general absorption of light varies with the different pigments. Their varying complexity is another factor.

Many yellow pigments reflect actually more red and green light than the majority of the bright red and green pigments, while the absorption of blue and violet is often very perfect. Therefore when photographing them by either red or green light they often photograph lighter than do the reds and greens, while when reproduced by the ordinary plate they are very dark. On the other hand many pigments, blues and greens in particular, absorb a considerable proportion of all colours, while the reflection extends over a large part of the spectrum, and in consequence the contrast effects that can be obtained with them are not so striking as in the case of most yellows, reds and oranges.

A. J. BULL.

## THE ACTION OF PLANTS ON A PHOTOGRAPHIC PLATE IN THE DARK.

A Paper read before the Royal Society, by whose courtesy the illustrations are reproduced.

It has been shown in former papers that wood has the property of acting in the dark on a photographic plate, when placed in contact or in proximity to it. Not only does wood act in this way, but leaves, seeds, roots, bulbs, and, in fact, with only few exceptions, all vegetable substances act in a similar way. The more important bodies which are without this property are starch, celluloid, gum, sugar, pith, and pollen. To obtain this action on a plate it is necessary that the body used be tolerably dry, or else the moisture contained in it will act on the gelatine of the photographic plate and destroy the picture. The time necessary for the exposure to the plate varies from a few minutes to eighteen hours or more. To quicken the action, heat may be applied, but the temperature must not be above 55 deg. C., nor the time of exposure, under ordinary circumstances, longer than eighteen hours, or the photographic film will be injured. Any ordinary rapid photographic plate may be used, and its development is exactly the same as that of an ordinary picture. The best and most general method of driving vegetable substances before exposing them to the photographic plate is to place them between pure white blotting-paper and subject them to considerable pressure, say from 1 to 5 or 6 tons per square inch. This process has also the advantage of giving a second picture, for it is found that the liquid which has been expressed and absorbed by the blotting-paper is capable of acting on a photographic plate, and that it gives a good representation of the plant from which it came (Plate 19, fig. 1, and oak leaf).

Since different woods are capable of acting on a photographic

plate it was to be expected that leaves, stems, flowers would do the same. This has been found to be the case, and the action has been traced from its commencement in the sprouting embryo of a plant till after its death. Postponing for the present the full discussion of the cause of this activity of vegetable matter on a photographic plate, it may be assumed as a working hypothesis that the active substance is hydrogen peroxide. As far as the activity of a plant goes, it is comparable with that of hydrogen peroxide. For instance, if one part of pure peroxide be dissolved in one million part of water it is sufficient to enable the solution in twenty-four hours at ordinary temperatures, even when the plate is  $\frac{1}{8}$  in. above the liquid, to give a marked action on the plate; and, on the other hand, a seed leaf of a runner bean weighing only 0.02 gramme can give a similar effect.

Taking now the case of a bean, both the broad and the runner bean act in the same way; the cotyledons, when tested by bringing them in contact with the photographic plate, either whole or in a crushed state, are always found to be quite inactive; the plumule and radicle before growth has begun is also without action, and even when growth has just commenced and the plumule lengthened 2 or 3 mm. it is still apparently unable to act on a plate, but as soon as plumule and radicle have increased in length about 15 to 20 mm., then it has become distinctly active. The following experiments illustrate this point:—

A plumule and radicle 8 mm. long, taken from a dry bean, was entirely inactive. Another bean which had been in moist soil for

Fig. 1.

Fig. 2.

--Fig. 3.--

--Fig. 4.--

Fig. 5.

Fig. 6.

Fig. 7.

four days, and was 15 mm. long, and just beginning to grow, was still unable to act on a photographic plate, but in another case in which the plumule and radicle had grown to the length of 19 mm. there was a faint action on the plate, and where the growth had extended to 80 mm. the liquid from this plant was distinctly active. Finally, a young bean plant, 170 mm. long, contained a liquid which was very active. The cotyledons remain always quite inactive. Wheat in its ordinary dry condition is without action on a plate, but if allowed to sprout by being placed in moist sand for about two days the shoots on being squeezed between paper show considerable activity. In fact, it appears that all seedlings contain in every part, plumule, radicle, and seed leaves, a juice which is capable of acting on a photographic plate. If seedlings be grown in the dark they still have this power.

In addition to the bean and wheat, other seeds and fruits have been experimented with, specially acorn, horse chestnut, pea, barley, almond, and many others, and the conclusion is that in their dry state they are devoid of all power of acting on a photographic plate, but that as soon as growth commences this power appears.

Supposing, as has more than once been suggested, and is strongly urged by Usher and Priestly,\* that formaldehyde and hydrogen peroxide are the first products of growth, this action on a photographic plate is exactly what would occur. At the same time it must be remembered that terpenes and resins, which are so commonly present in plants, can even in very small quantities, either directly or indirectly, give rise to this body.

Nuts such as walnut, Brazil nut, Barcelona nut, etc., act like seeds; the endosperm is inactive in its original state, but if charred

as nuts often are, with a considerable amount of oil, this, on exposure to the air, oxidises and becomes very active. For instance, if the kernel of a Brazil, Barcelona, walnut, or almond, nut be taken out of its shell and at once crushed between blotting-paper, neither nut nor expressed liquid are active, but if the paper with the expressed liquid in it be kept for a short time exposed to the air, then it gives a very dark picture. If the nut be extracted with ether and the solution evaporated, the residue becomes strongly active. Of all nuts and seeds examined, castor-oil seed appears to be far the least active; the expressed liquid from it may be exposed for a month or more, and it is still without the power of acting on a plate.

The examination of different bulbs has shown that the fleshy scales forming them, from centre to outside, are active, but that the nucleus of the future plant which it contains, if in its primary state, is inactive like the plumule in a seed, but when growth has commenced it is active. This is well seen in the snowdrop, onion, and shallot; the shoot, if not visibly grown, is quite inactive. The amount of activity of different bulbs varies very considerably, the snowdrop bulb is slightly active, whereas the narcissus and the tulip bulb is much more so. This variation may probably depend to a considerable extent upon the state of development of the bulb. In the case of the crocus, which has a solid bulb, its activity is like those above mentioned. The tuber of the potato squeezed between blotting-paper gives a very active juice, the Jerusalem artichoke a juice which is much less active. If bulbs or tubers be dried even at ordinary temperatures they lose their activity. The rhizome in different plants varies much in its activity, and probably in the same plant at different times of the year; in the iris it is but very slightly active, in sea kale it is more so, and in the Pteris it is very active.

Fig. 9.

Fig. 10.

Fig. 11.

Fig. 12.

Fig. 13.

Fig. 14.

Fig. 15.

Fig. 16.

A considerable number of different roots have been experimented with, and in all cases it has been found that the root has very considerable activity; in fact, the root of some of the larger trees—for instance, Scotch fir—gives a picture similar to that given by the wood itself.

There are some interesting points with regard to the shells which protect different seeds and fruits. The outside is quite inactive; even if laid on a plate for a long time it produces no effect. The horse chestnut is apparently an exception, but in this case the out-

side skin of the nut is very thin, and the brown material immediately beneath is very active, but the nut itself, as before stated, is quite inactive.

With regard to the woody substance which forms the substance of a shell, it consists of at least two distinct substances, one of which is able to act on a plate, and the other is not able to do so.

For instance, in a cocoanut shell, the constituent of the shell which is lightest in colour is quite inactive, and the darker part is very active. Again, in the butter nut, Fig. 2, the red portion of the

shell is quite inactive, while the dark part is strongly active. In the Brazil nut the same thing also occurs, the central dark layer being very active, and the outside part is entirely without action. In fir comes the same kind of thing occurs; the axis of a cone consists of materials varying but slightly in colour, but very considerably in their power of acting on a plate. In the case of the almond shell it is throughout perfectly inactive.

Both the shell of the acorn and of the Barcelona nut consists of two layers, which are easily separated, the outside one is inactive and the inside one is active. Immediately within the shell of a nut there are one or more integuments, and they have very different powers of acting on a plate. For instance, in the cocoanut there are three integuments, the one next to the shell is very thin and of a whitish colour, the next one is much thicker and of a brown colour, and the third one is very thin and also brown in colour. The thin integument next the shell and the thick brown one in contact with it are both active, but the third layer is without activity. There is also a thin skin adhering to the kernel; this is also quite inactive. This variation in the action of different parts of a nut is well shown in Fig. 3, which represents the two halves of a walnut split through the middle; from one half the kernel has been removed, but not from the other half; the kernel filling up the shell is quite inactive, but the lining to the empty shell is quite inactive.

Actions of the same kind occur with broad and runner beans and other seeds; the outside, the testa, is inactive, and the inner layer is active.

Fig. 4 is a picture given by a section of a broad and a runner bean, and Fig. 5 a section of a horse chestnut.

On examining the flowers of different plants the petals in all cases have been found to be active. They are best dried by squeezing between Ford blotting-paper, and a picture can be obtained both from the petal itself and from the expressed juice in the paper. In many cases a characteristic picture is obtained from the paper. Fig. 6 is one obtained from the paper on which an Auricula flower has been squeezed, and Fig. 7 is from an Oriental poppy. Fig. 8 is from the petal of a viola. The colour of the petal does affect the result. White, blue, and pink petals of the Canterbury bell, red and white rose petals, dark purple and yellow viola petals, and many others, all give similar results, and all, as far as rough experiment goes, appear to be active to about the same extent. They show, however, greater activity than an equal area of the leaf of the same plant.

The pistil in a number of plants—for instance, poppy, lily, cactus, tulip, iris, etc.—were examined, and in all cases were found to be very active. The stamens of different plants when squeezed

were found to be very active but pollen, on the contrary, when examined alone was always found to be quite inactive. That from the sedge, hazel, Scotch fir, *Pinus pinaster*, *Pinus cembra*, and many other plants was examined.

*Leaves.*—Carrying the investigation on to leaves, large numbers have been experimented with, and all have been found to act on a photographic plate. The amount of action naturally varies with leaves from different plants; where there is much sap juice there is generally much action. If a leaf be simply dried its activity is much lessened, or may be clearly destroyed, and its surface is rendered uneven; but even in old and dried leaves a very appreciable amount of activity remains. For instance, beech leaves picked up off the ground were found to have about the same degree of activity as the ordinary green leaf, and a canna leaf which had been between blotting-paper in a press for one and a half years, and other leaves which had been pressed for two to three years, still were able to give a faint picture. If these old leaves were slightly moistened before putting up with a photographic plate, this activity was considerably increased (Figs. 9 and 10). Also it is interesting to note that if a slit be cut in the dry leaf, this becomes in the picture very visible. Fig. 11 appears as if an active emanation had taken place from the body of the leaf. The best way of obtaining satisfactory pictures of leaves is to subject them to considerable pressure between white (Ford) blotting-paper; this, of course, squeezes the leaf juice out, and the leaf is left in such a condition that after standing in the air for a short time it may be put up with the photographic plate. Whether the squeezing should be repeated, and whether the pressure should be a quarter of a ton or six tons, depends on the nature of the leaf experimented with. This way of drying a leaf has also the advantage, as previously pointed out, of giving a second picture, which is often a very interesting one, and is simply obtained by exposing the paper with the absorbed sap from the leaf to a photographic plate.

Figs. 12 and 13 are from the leaf itself, black currant, and Figs. 14 and 15 are pictures of the same leaf, but are from the paper between which it was squeezed. As further illustrating the nature of the pictures obtainable by these processes, Fig. 16 shows the front and back of a beech leaf taken direct from the leaf. Ferns and mosses also give interesting results, but these will not be dealt with in the present communication.

The above investigation has been carried out in the Davy-Faraday laboratory, and my thanks are due to the managers of the Royal Institution for the use of their laboratory. I am also much indebted to my assistant, Mr. O. F. Bloch, who has been of much help to me, and has made all the photographic pictures for the illustrations.

W. J. RUSSELL, F.R.S.

## FOREIGN NOTES AND NEWS.

### Oil-Ozobrome.

M. Puyo, in describing, in the current number of the "Revue de Photographie," his first essays in the combination of oil printing and ozobrome, says that photographers, like all human groups, are divided into two schools. The one includes those who make good negatives, or, finding their negatives good, do not alter them. The ozobrome process is for this class. The second school includes those photographers who make bad negatives, or who find the negatives that they have made bad. These are those who wish to control the negatives by correcting the values, etc. They have not any respectful deference to this classic process of carbon.

But there is a new process, full of resources—viz., oil. For the last three months I have used this process, and the idea naturally occurred to me to combine it with ozobrome. To this end then I applied to a postcard representing one of our choreographic glories, a sheet of gelatinised paper, soaked in ozobrome solution. After a few minutes' contact I separated the two papers, and having washed and dried the gelatinised paper, I attacked it with a brush charged with lithographic ink.

At first sight, if this inking up should be easy, the results would be grand. The great discovery required more trouble. I had a lot of trouble, however, but with insistence and application it was

at length accomplished. Certain parts of the image were good, others but mediocre. The method was not a complete success, but the first trial was very encouraging, and if M. Manly will give me the help of his special knowledge I hope to arrive at a satisfactory result. The ozobrome solution contains apparently a little alum. The difficulties perhaps arise from this, for experience has proved to me that aluminised gelatine takes ink badly. Then it may be advisable to study the action of the bath. All these trials would be very long, and I do not know when oil-ozobrome would see the light of day. I cannot fix a date.

"There is, however, no reason why ozobrome should not be applied to all papers in which there is a colloid insoluble in cold water; in other words, in all papers for development by soaking, pure gum paper excepted. And, in fact, I have made a hasty test to transfer the image of a bromide postcard to a fragment of Fresson paper. It is obvious then that M. Manly's discovery is of general interest, and may shortly receive the most interesting applications."

### Flashlight.

The following notes are abstracted from a little pamphlet published by Herr Pettauer descriptive of the use of a special flashlight powder

made by Seib, of Vienna, but they are also generally applicable. The necessary quantity of flashlight powder can be calculated from the following formula,  $M \times E^2 \times V$ , in which  $M$  is the quantity of powder required to give a fully-exposed negative, when burnt 1 yard from the sitter with a lens working at  $f/9$ , which may be considered as equal to 2 grains of pure magnesium.  $E^2$  is the square of the distance, and  $V$  the ratio of exposure for the stop used; thus, assuming that the sitter is 3 yards from the light, and  $f/16$  be used, the quantity of pure magnesium required would be  $2 \times 3^2 \times 3\frac{1}{2} = 57$  grains. Unless a diffusing screen be used, the shadow cast by a sitter is always very heavy, and the two following simple rules are given to avoid the too great prominence of the same. If the source of light is placed lower than the highest point of the sitter, then the background should be placed nearer the object. If, on the other hand, the source of light is placed higher than the highest point of the sitter, then the background must be further away.

#### Testing Ortho Plates and Screens.

M. Monpillard describes, in the "Revue des Sciences Photographiques," his method of testing ortho plates and colour filters. The source of light is the Fery acetylene standard which, however, is not calibrated to diffused daylight. The filters used for splitting up the spectrum are a yellow, consisting of a 5 per cent. solution

of neutral chromate of potassium in 10mm. thickness; this absorbs the whole of the violet and blue up to  $\lambda$  488. A blue-violet filter is a 6.6 per cent. solution of ammonio-sulphate of copper, which transmits the blue-violet from  $\lambda$  400-470. A blue filter of 0.1 per cent. of esculine transmits from  $\lambda$  437 to  $\lambda$  480. A green screen is made with

Cupric chloride pure (50 per cent. solution).....	30 c.c.s.
Hydrochloric acid .....	5 drops.
Potassium chromate (5 per cent. solution) .....	4 c.c.s.
Distilled water to .....	50 c.c.s.

In 10mm. thickness this solution transmits from  $\lambda$  485 to 600, with a maximum from  $\lambda$  530 to 570. An orange filter is made with

Potassium bichromate (5 per cent. solution) .....	4 c.c.s.
Potassium permanganate (1 per cent. solution).....	1.25 c.c.s.
Distilled water to .....	50 c.c.s.

This transmits the whole of the more refrangible rays to  $\lambda$  570.

The plates are exposed behind the rotating sector, the opacities plotted out, and the sensitiveness of the plates and the increase of exposure with different screens determined. The use of so many colour filters and the neglect of the spectrum composition of the acetylene standard makes this process less practical than that adopted by Messrs. Mees and Sheppard.

## THE "MECHANICAL" ACTION OF LIGHT ON THIO-RESINATES.

THE following abstract is taken from a paper by F. Alefeld in the "Chemiker Zeitung," in which he describes at great length this somewhat curious process. He points out first of all the researches of others, dating back to 1728, on the so-called photo-crystallisation—that is, the formation or alteration of crystals under the influence of light. It is a well-known fact that if a few pieces of camphor are placed in an empty well-corked glass bottle, in a short time a beautiful crop of crystals forms on the side of the bottle, and generally on that side which is exposed to the light. This was described by Schaum and Raikow to heliotropic crystallisation. Alefeld has repeated these experiments under conditions which included the action of heat, and found that this heliotropic crystallisation is actually due to that side of the bottle which is exposed to the light being colder than that which stands near to the wall of the house. From his experiments, however, the author was led to believe that there was not "any action on an existing sublimation, but the production of a movement, a diffusion, by the action of light, and that it could be used for the production of prints by light."

Briefly, the new reproduction process is as follows:—Solutions of certain compounds, which on heating leave behind a highly coloured ash, are coated evenly on glass, and after drying exposed under a negative. If now the plate, without any other treatment, be heated, at a given moment when the last traces of solvent have most completely evaporated, the positive image will appear in sharp relief, the shadows of the positive being in relief and the high lights sunken. There is obviously on the exposed parts more of the coating than on the unexposed, and if the plate is heated till the organic substances are burnt, the ash that remains gives an exact positive from the negative—the picture is seen as a kind of transparency, a dark drawing on the transparent glass.

"The only explanation which can be given from all the observations of the formation of the picture according to this process is that under the action of light the substances dissolved in the coating solutions migrate from those parts unaffected by light to the exposed parts, so that with the duration of exposure more and more accumulate under the negative-lights, whilst the negative-shadows become always more free from the same."

#### Diffusion Images.

Although this "diffusion" or "migration" would apparently require such a condition of the film that the particles would have a certain freedom of movement, and that therefore the film must be damp, the author states that the films must be dried at 212 deg.

Fahr. for fifteen to thirty minutes; this enables intimate contact to be obtained between negative and positive film.

This "mechanical light-sensitiveness," as the author calls it, is not confined to silver salts, "but is very widely, perhaps universally, distributed." The essential properties of the compounds which can be used for this process are:—

1. As the pictures must be heated after exposure to a red heat only glass, porcelain, metals, or enamels, etc., can be used as the support, and the compounds must be such as can be coated on these in thin and even films; aqueous solutions, therefore, are mostly excluded.

2. The solutions must dry on the support in amorphous, even, coherent films, so that they can be pressed into contact with the negatives without adhering to it; yet when this state of dryness is attained the film must not present too great a resistance to the diffusion.

3. When "burnt-in," the image must remain sharp and clear, and the compounds must not remain long in their melted condition, otherwise the details will run together. For the same reason the adhesion to the glass or support must be sufficient.

4. Finally, as strongly a coloured ash as possible must remain behind, so that the image may be clearly visible, and this residuum must adhere sufficiently to the support.

The lustre colours which have been used for a long time in ceramic work for the decoration of glass and porcelain are very satisfactory. They are usually resinates or thio-resinates, or similar compounds, are easily soluble in ethereal oil and other compounds, and when they contain metals they leave behind an ash which consists largely of oxide.

The glass or support is coated with the requisite solution, dried for fifteen to thirty minutes at 212 deg. Fahr., exposed for about half an hour to bright sunlight, and then burnt in. "Extraordinarily sharp images are obtained, which reproduce the smallest details of the negative—for instance, very small writing, the letters of which are only fractions of a millimetre high. The new process is by this distinguished from all existing processes for the production of burnt-in photographs, which only give somewhat fuzzy pictures."

Unfortunately no pure whites are obtainable, as, so far, it has not been possible to obtain, even with long exposure, the unexposed places quite free from light-sensitive salts.

"All solutions which have actually been tested so far prove to be light-sensitive in this sense—that is, they are capable of giving the

'mechanical' light action by diffusion." This mechanical light-sensitiveness was observed with the resins or thio-resins of the following elements:—Aluminium, antimony, arsenic, barium, bismuth, boron, bromine, cadmium, calcium, cerium, chromium, chlorine, cobalt, copper, gold, iodine, iridium, iron, lead, magnesium, manganese, mercury, molybdenum, nickel, niobium, osmium, phosphorus, platinum, potassium, rhodium, ruthenium, selenium, silicon, silver, strontium, sulphur, thorium, titanium, tin, tungsten, uranium, vanadium, zinc, and zirconium.

It was also found that a pure resin solution possessed this mechanical light-sensitiveness; it was observed, too, with resin dissolved in turpentine, Venice turpentine, the oils of aniseed, rosemary, and lavender, with natural asphalt dissolved in chloroform, benzole, oil of turpentine, etc., collodion in ether-alcohol, in aqueous solution of silver nitrate in gum, ferric chloride in water, solutions of resin in borax, solution of malt extract. The best results were obtained with those solutions containing resin.

### Exposures.

The duration of exposure depends on the quality of the light, the character of the solution, and especially on the drying. When the plates are dried for fifteen to thirty minutes at 212 deg. Fahr., about half an hour in direct sunlight is correct, but the commencement of diffusion can be seen much earlier, even after thirty-five seconds' exposure, with plates which had been exposed to the air for ten minutes, without drying by heat, showed the action in ten seconds. Plates dried at 212 deg. Fahr. for fifteen minutes showed the first action in direct light in four minutes, when dried in two minutes, and with poor magnesium light in one minute.

With very long exposures, several hours in the strongest sunlight, the burnt-in picture becomes very rich in contrasts, and the halts appear to accumulate in the middle of the lights in thin, dark lines, so that after several hours of the most intense exposure, i.e., drawings, instead of exact copies, were obtained after burning in.

"The low sensitiveness to even light—that is, light which is not separated into bright and dark rays by passing through a negative, whether direct or reflected diffuse sunlight, or arising from any other source—is extremely convenient as all the operations—the preparations of the solutions, coating the plates, the burning in after exposure—can all be done by daylight without any harm resulting."

It is interesting from a photo-chemical point of view that with normally dried plates a chemical action of light—that is, change of colour or darkening—was never observed even with several hours' exposure to the strongest sunlight. On the other hand, plates which were dried too much, especially when the solutions dried very hard and firm, or when collodion was added to obtain the same effect, after a short exposure showed chemical action as a dark image on a light ground. The image was then visible, but not in relief, and completely disappeared in burning.

"These observations may perhaps explain that, at least in the present case, light acted in a distributing manner as long as diffusion was possible, and that as long as this took place there was very little chemical action. If, on the other hand, diffusion was prevented, the light was converted into chemical energy. In substances of greater light-sensitiveness it may be different, but may be comparable. Perhaps the ripening of gelatino-bromide of silver may be explained by assuming that strong drying of the film and further consolidation of the silver bromide grains produces greater insolubility, and thereby increased chemical light-sensitiveness."

In order to determine whether the action observed was due to light or heat, plates were exposed under glass ruled with black lines three millimetres wide, with strips of blue, yellow, and red glass laid over the same; an image was obtained in one minute, five minutes, and two hours respectively. An alcoholic solution of iodine prevented any action.

### A "Mechanical" Change.

To prove that mechanical migration or diffusion and not photo-chemical action was the cause of the phenomena, the author refers to the relief obtained, and the darker colour of the shadows is ascribed to the particles having migrated from the high lights. As a further proof, he cites that between lights and shadows there is always a dark outline or a lighter line, the edge of the shadow

are darker, and that of the lights lighter than the other portions. A further proof is stated to be that the image is seen better on a smooth than on a rough support; any powdery deposits prevent the formation of the image.

That oxidation or reduction is not the cause is proved, because when burnt-in this action would be general, and no image would be seen. If the mechanical migration theory is correct, then one exposure should have no effect on a second exposure, and the particles which had migrated during the first should again make the grand trek during the second exposure. Unfortunately a second exposure did not obliterate the first picture, but the author explains this on the ground that the migratory power was lessened through further drying or resinification during the first exposure, and he says: "Perhaps there is also with the mechanical a little chemical action, which is the obstacle to complete success."

If the author's theory is correct, one should be able to quantitatively determine the truth of his statement and arguments, because if a non-volatile substance was used, it should be possible to find more of it on the exposed than on the unexposed parts. Sheets of gelatine 6 by 6.6 cm. were fastened with Venice turpentine to glass and coated with a solution which would only leave metallic silver as a residue. The exposed and unexposed strips were then incinerated, the ash dissolved in nitric acid, and the quantity of silver titrated with ammonium sulphocyanide solution, and the amount of silver found to be:—

Exposed Strips.	Unexposed Strips.
1. 0.05594 gm. Ag.	0.00303 gm. Ag.
2. 0.03524 " "	0.00292 " "
3. 0.03703 " "	0.00216 " "
4. 0.00526 " "	0.00221 " "

In Nos. 2 and 3 only thin coatings were used.

The author comes to the final conclusion that in consequence of the inherent faults the process will be of no practical value, but that it is sufficiently interesting from the theoretical point of view to warrant publication in order that others may pursue the subject, of which he has no further time.

### PLATE-SPEED NUMBERS.

A CIRCULAR newly issued by Messrs. Wratten and Wainwright, of Croydon, supplies in convenient form information for which application is frequently made, and in regard to which a considerable diversity of opinion exists—we refer to the speed numbers which must be given to a plate according as the Hurter and Driffield, Watkins, or Wynne system of exposure is adopted. Messrs. Wratten give the following relations between these three systems, the correctness of which they have proved in regard to their own plates. It is to be supposed that there would not be an appreciable departure from these ratios in the case of any commercial plates. It is Messrs. Wratten's intention to issue periodically a circular which shall bring this multi-speeding of their plates up to date. It will be sent to all those who are upon their addressing list.

The Wratten speed numbers are found by the method laid down by Hurter and Driffield, which gives a number known as the Inertia (i), which is a measure of the insensitiveness of a plate.

H. and D. No.—If 34 be divided by this we obtain the "actinograph" number, which we call "H. and D."

Thus, if the inertia be  $\frac{1}{i}$ ,  $\frac{34}{i} = 136$ , and the plate is "H. and D." 136.

The inertias are found by the developer given, metol-hydroquinone, without bromide.

P. No.—A number which corresponds to the P. No. of Mr. Watkins is found by dividing 50 by the inertia—

Thus— $\frac{50}{i} = 200$ , and the plate is 200 "Watkins."

This method has been approved by Mr. Watkins.

Wynne No.—According to the original method of the Infalible Exposure Meter Co., the Wynne F. numbers should be found by multiplying the square root of the Watkins number by 8.

Thus— $\sqrt{200} = 14.1 \times 8 = F. 112.8$  Wynne.

This is the method we have employed hitherto.

Alterations in the paper employed in meters have produced an alteration in the ratio, and we are informed that the Wynne Speeds are now to be found by multiplying the square root of the Watkins number by 6.4.

Thus— $\sqrt{200}=14.1 \times 6.4 = F.90$ .

This is the method which we shall employ in future.

#### PHOTO-TELEGRAPHY.

THE recent accounts of the advances made by Professor Korn in his methods of transmitting photographs by electric communication have been discussed in the newspapers for the past week or two, and will be the subject of an article in our pages at an early date. But Professor Korn is not alone in the field. According to the Paris correspondent of the "Daily Telegraph," M. Edouard Belin, an engineer of Nancy, who, we see, is a member of the Société Française de Photographie, has an even more startling discovery to announce. The Munich professor is able to telegraph a photograph. Mr. Belin says that he can photograph by telegraph. He places his camera in a spot A, opposite the object which it is intended to photograph. Some equivalent of a sensitive plate is placed at B. The points A and B, directly connected by an electric current passing along a wire, may be "at any distance." You press the button at A, and the sensitive plate at B takes the picture instantly, miles away. This sounds marvellous enough, but it is not all. The picture taken at B is no negative requiring to be developed, but a positive image, which is, ipso facto, fixed, and is a permanent photograph. M. Belin withholds the secret of his invention, and one can, therefore, only describe, not explain, the apparent miracle. He says that he has carried out many successful experiments in the last year. His first achievement was to telegraph merely one black dot from one sheet of paper to another, at a distance of nearly three hundred miles, over a public wire lent by the Postmaster-General. The transmitting and receiving apparatus were both placed in Paris. But they were connected by a telegraphic line running to Havre and back. The black dot was transmitted by this roundabout route instantaneously on the blank sheet of paper. The first experiment was effected with M. Belin's first instrument, which he calls his "simplex" machine. He afterwards built "multiplex" apparatus, with which he took complete pictures at a distance. His phototelegrams are printed, not as those of Professor Korn, in lines, but in dots, and there are 6,400 of the latter in the most complete image which he has yet obtained. The phototelegrams can be produced directly not only on paper, but also on copperplate, which can be at once treated with acid and used for photogravure.

In a short while M. Belin will attempt an experiment on a larger scale than he has yet tried. He will endeavour to photograph a human face over a circular telegraphic line from Paris to Lille, Brest, Bordeaux, Marseilles, Nancy, and back to Paris again, and he hopes to "loop the loop" successfully. The engineer's feats take one's breath away, but he is bent on still greater. He has studied the problem of transmitting successive images, and "is on the brink of a solution." This means that he may realise a far greater miracle than that of the telegraph or the telephone, and greater even than phototelegraphy. "When his apparatus has been improved to the extent of producing ten successive images in one second the problem of sight at a distance will have been solved. A scene photographed at Nancy will be instantly printed on a revolving roller in Paris, and events happening in one spot will be visible almost at the same instant to persons in another." Finally, M. Belin "proposes to apply his invention to the telephone, and hopes that shortly one will be able to see as well as talk to a friend over the wire."

#### A SEQUEL TO THE CANVASSING FRAUDS.

THE most interesting photographic studio in Sheffield last week was situated at the Central Police Parade Yard, Castle Green, which presented an unaccustomed scene. There, in long rows across the floor, and resting against the walls, were hundreds of enlarged photographs, in varying stages of incompleteness, of young men and maidens, old men and children, in all sorts of possible and impossible "artistic" poses. On a large table in one corner of the parade ground lay large numbers of the original photographs. In and out among the rows of picturesque studies walked people, mostly of the working classes, anxiously looking for lost relatives or friends, or

for reproductions of their own faces and figures. They were there at the invitation of the police, who recently seized the photographs at the offices of the "National Fine Art Company," in Pinestone Street. The distinguished members of the National Fine Art Company have disappeared. Their business was apparently conducted on simple lines. They or their agents visited the homes of the poorer classes, and, it is alleged, offered to provide them with magnificent enlargements of photographs of themselves or other members of their families for virtually nothing—all to advertise the firm. But presently the representative of the Fine Art Company called again—this time with a half-finished enlargement enclosed in a most attractive frame. Of course—it is charged against them—Mr. Smith must pay for the frame, and must pay a part of the amount before the completion of the work of art. In a great many instances this was done, but most of the various Mr. Smiths are still waiting for the completed and beautifully framed enlargements. In many cases the sums required and paid reached as much as 15s. and 18s.

#### MR. J. T. SANDELL.—AN APPEAL.

THE following sums have been sent to Mr. Thomas K. Grant, in further response to the appeal which has been made by him and Mr. J. B. B. Wellington in our columns and those of our contemporaries for some weeks past:—

	£	s.	d.
C. Churchill	1	0	0
Blaigowrie Photographic Society (per John B. MacClachlan)	0	16	0
Glasgow and West of Scotland Photographic Association (per A. G. Watson)	5	0	0
Preston Scientific Society (per A. W. Cooper)	0	15	0
Amount already acknowledged	7	11	0
	134	9	6
	142	0	6

## Exhibitions.

#### LANCASTER PHOTOGRAPHIC SOCIETY.

The awards made by the judge, Dr. A. T. Lakin, of Manchester, in the open classes were as follows:—

Class A (Landscape, Seascapes, and River Scenery).—Silver Plaque—"The Landing Place," C. D. Baxandall, Lancaster; Bronze Plaque—"Departing Day," Harry Lindoe, Sunderland.

Class B (Portraiture and Figure Studies).—Silver Plaque—"Kartoffelausmachen," H. Y. Summons, Sandhurst; Bronze Plaque—Withheld.

Class C (Architecture: Interior or Exterior).—Silver Plaque—"Old Durham," H. Lindoe, Sunderland; Bronze Plaque—"A Bit of Old York," A. W. Walburn, West Hartlepool.

Class D (Lantern Slides, set of four, any subject).—Silver Plaque—"Departing Day," Fred Judge, Hastings; Bronze Plaque—"A Confidential Chat," A. G. Thistleton, Newton Heath.

Class E (Postcards).—Silver Plaque—"The Lavatorium, Gloucester," Rev. E. T. Clarke, Tiverton; Bronze Plaque—"Church House," T. H. Boycott, Bootle.

#### WELLCOME PHOTOGRAPHIC CLUB.

The sixth annual exhibition of members' work was opened on Saturday, December 1, at Dartford, by Mrs. Wellcome, in the presence of a large gathering of members and friends. The exhibits, 172 in number, were displayed on the walls of the spacious gymnasium in the grounds of the Wellcome Club and Institute. A high standard of artistic and technical excellence was reached; and Mr. A. Horsley Hinton, who very kindly consented to act as judge, made the following awards:—

Class A (General).—Plaque (No. 41), "A Road in Flanders," G. T. Gale; plaque (No. 75), "Chislehurst Common," S. F. Morgan; plaque (No. 126), "Sunset," F. C. Starnes. Honourable Mention.—(No. 63), "Outward Bound," R. E. Jackson; (No. 116), "Anstey's Cove," H. C. Sayer; (No. 138), "Child Study," A. Wilson.

Class B (Holiday Sets).—Plaque (No. 148), "Thames to Tyne," R. E. Jackson. Honourable Mention (No. 152), "To Edinburgh by Water," F. C. Starnes.

## THE NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

On Thursday evening of last week the N.M.P.S. opened its annual display of prints and slides. The former reputation of this energetic society is, perhaps, surpassed on this occasion. What strikes the public is the general air of maturity in the work shown. Have the N.M.P.S. no beginners at all, or are their elementary members all prodigies? There is no selecting committee; everything entered for exhibition, and the result is a first-class and highly interesting display of technical and artistic performance, local though it also is. Out of 124 pictures, 120 are bromide prints, a fact that says something for the popularity of this process. Only four, however, were silver prints, which shows what a change has come over the spirit of amateur photography since 1888, when, we were told, the majority of exhibits of the N.M.P.S. were upon P.O.P., and the hanging was accomplished by fastening the prints on to strings with tacks. Of course, there were no frames, and the pictures danced up and down before the gaze of their admirers. That was in the society's first year. Gum-bichromate is very healthy in this show, for, out of fifteen specimens, two have awards and two have certificates. Ozobrome is represented by eight samples, carbon by thirty-six, and platinum by six. The awards were given to the following works:—"Niagara Falls," by T. Bowden, a highly pictorial view, full of nice feeling; "A Rural Sheltered Scene," by H. Stuart, a gum print of much freshness of style; "The River in its Childhood," by A. H. Piddington, another gum, of charming subject with a good composition; "White Currants," by D. Fox, highly realistic, but not without reality; "When Shadows Lengthen," by A. G. Lawson, a delightful carbon print; and "Hill and Dale," by W. Pringle, of which the time exactly may be said. Besides these, "The Medway at Rochester," by A. H. Piddington; "A Low-roofed House, etc.," by H. Stuart; and "A Venetian Byway," by W. Pringle, as well as a capital set of slides by F. P. Bayne, representing birds' nests, were highly commended" by the judges, who, upon this occasion, were Mr. Reginald Craigie and Mr. Furlley Lewis. The list of awards, however, by no means comprises all the fine things. We were much struck by "A Glimpse of the Moor," by E. R. Matlocks, and by the excellent works by H. W. Fincham. The first of these was titled "London's Justice," and represents one of the romantic corners of which this great city abounds for such who have enthusiasm to meet them out. Mr. Fincham penetrated into the "ruins" of the old Bailey (which reminds us that the Editor of "Photography" has been here this year), and has found a nook where the dome and the gilded figure of the new Central Criminal Courts tower with effect over dark houses and an open space covered with interesting litter. The same worker's "Ruined Tomb" is highly worthy. The President, Mr. C. Beadle, has some good mountainous subjects, "Hill Cattle" being perhaps the finest. His portrait of "Miss Milfax" has charm, dignity, and quality. A pair of naked twins, whose laughing faces show over the hedge of a bath, is the subject of "Mixed Bathing," by G. E. Williams. It is the favourite with visitors. The work of Mr. Mummery, Mr. S. E. Wall, and Mr. Merchant is too well known to require detailed description. Very naturally it is not entered for competition, but a liberal show of it is a great distinction to the walls. The Record Section keeps up interest. The present numbers range from 185 to 232, from which it will be seen that this excellent and valuable work goes on apace. Indeed, the antique corners of North London seem to be far from exhausted by the North Middlesex searchers and recorders.

## CATALOGUES AND TRADE NOTICES.

Messrs. L. GAUMONT and Co., 22-27, Cecil Court, Charing Cross and London, W.C., are very quickly in line with public events assuming a new film of the Santos-Dumont airship ascents. A new catalogue gives particulars of the latest record, which will doubtless be esteemed by cinematographic entertainers.

CHRISTMAS PRESENTS.—Messrs. W. Butcher and Sons, in the December issues of their "Camera House Journal," offer the photographic dealer particulars of a number of attractive selling lines in photographic and allied goods. There are also some bargains in photographs and model toys.

DR. TRAUBE'S New Process.—The necessary plates and solutions of the above new process are supplied by the well-known plate worker, Herr Perutz, 50, Dachauerstrasse, Munich.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received from November 19 to 24:—

CINEMATOGRAPHS.—No. 26,374. Improvements in cinematographs. Arnold Thackall Browett, 18, Hertford Street, Coventry.

PRINTING FRAMES.—No. 26,423. Improvements in photographic printing frames. Aaron Henry Howell and Henry Handyside Bates, 38, Chancery Lane, London.

CINEMATOGRAPHY IN COLOURS.—No. 26,671. Animated pictures in colours by direct photography. George Albert Smith, Laboratory Lodge, Roman Crescent, Southwick, Brighton.

## COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

PRINTING FRAMES.—No. 4,527, 1906. The invention is a printing frame of the kind in which the back is made in several hinged pieces. In the present apparatus the ordinary pressure springs, having a horizontal movement, are used to hold the back from end movement. This is done by the spring fitting a groove in the back and a slot in the side of the frame, there being a pivoted catch to hold the pressure spring. Leon Faure, trading as Grey and Co., Bridlesmith Gate, Nottingham.

PRINTING FRAMES.—No. 4,730. The invention is a frame adjustable to hold various-sized negatives by means of sliding pieces with rebated edges. The sides are formed with slots or spaces, one end piece with a rebated edge on the underside, a sliding adjustment piece having a similarly rebated edge and provided with grooves engaging tongues on the side pieces, and means for locking the sliding piece in the required position. John Batty, 124½, Wells Street, Lozells, Birmingham.

DEVELOPING MAGAZINE.—No. 7,295, 1906. The invention is an attachment to a camera to which plates can be transferred and developed. The first claim is: Photographic apparatus comprising a magazine, adapted to receive plates arranged in a box that is formed with grooves in which the plates can slide, and is provided with a light-proof cover capable of being withdrawn when the plate box is within the magazine, and an adjustable blind controlling the mouth of such magazine, one edge of such blind being formed with a lip adapted to engage a suitably formed part of a camera into which plates from the magazine can be caused to pass when the blind is withdrawn to the necessary extent.—Cesar Motti, Villa du Ray, 15, Avenue Thiers, Grasse (Alpes Maritimes), France.

DEVELOPING ATTACHMENTS.—No. 22,590, 1905. A development chamber, comprising a guide frame for films, two slots for withdrawing black paper from the spools which are geared together by gear wheels or any other suitable device, and plates which can be used as a cover when folded and as walls of the charging chamber when in vertical position, and which is used in combination with frames provided with openings for introducing the hands. Nicolas Wladimoroff, 10, Rue Michel Charles, Paris.

RELIEF EFFECTS.—No. 11,072, 1906. The process for which a patent is claimed consists in making from any given photograph or other original—

A. An ordinary negative copy.

B. A positive copy on glass of the same size as A—that is, a transparency printed from A by contact.

These two, positive and negative, are placed in register with a space of a fraction of an inch between them and a photograph of the combination thus made is taken under special conditions of lighting.

The peculiar characteristics of the compound photograph of A and B can be seen by holding it vertically at arm's length in a room moderately lighted from one side, and between the eyes

and a wall of that room which is under its window and with its positive side turned toward that wall. In this position light coming through the window reaches the positive side of the compound photograph somewhat diagonally from above and causes the opaque leaf thereon to cast a shadow on the negative part, which shadow falls wholly or mainly upon the clear leaf of the negative part; but that shadow does not register with the clear leaf of the negative part, and its boundaries are graduated and indefinite. Those portions of the clear leaf of the negative part which are not covered by that shadow appear to be light, while that portion which is covered by that shadow is variably dark in appearance, and the borders of the shadow gradually lighten off into the light of the clear leaf of the negative part of the compound photograph. That photograph can be held in such a position and such a light as that the shadow cast by the opaque leaf of its positive part will appear to fall entirely within the clear half of its negative part, or the compound photograph can be held in such a position and such a light as that the shadow of the opaque leaf of its positive part, while falling mainly on the clear leaf of its negative part, will lap over the tinted field of its negative part. In either case that shadow combines with the clear leaf and with the tinted areas of the negative part of the compound photograph to present the appearance of a relief photograph and the relief effect is rounded and artistic instead of being sharp and mechanical, as it would be if the two parts of the compound photograph had no distance between their films, even if they had been fixed together out of register with each other. John William Lloyd, 101, Beekman Street, New York, U.S.A.

The following complete specification is open to public inspection prior to acceptance under the Patents Act, 1907.  
CINEMATOGRAPHY.—No. 25,798. Gates for protecting the films of kinetograph series.

## New Books.

"The American Annual of Photography, 1907." New York: George Murphy. (London: Dawbarn and Ward.) 2s.

The text portion of this annual is made up, as hitherto with contributed articles and collections of formulae and tables. The former relate in the main to the practice of photography, as it is prevalent at the present time among amateurs. They contain little of permanent interest, and some things which betray the ignorance of the writer. For example, a person named W. F. Oliver, whose literary—or should it be scientific—contribution is entitled "'07 Pepper Sauce for Plain Roast of '05," courteously refers to the pioneer work in sensitometry as follows:—"Hunter and Driffeld" (Mr. Oliver cannot even quote a name correctly) "also ran, with a few high-flown nonsensical theories, something about the number of possible gradations in a picture." The illustrations are really a greater incentive to purchase the "American Annual" than the text, for among the many half-tone reproductions scattered through the pages there are a number which are quite excellent examples of photography with pictorial aims; though few, we must admit, which rise above the level of the many photographs to be seen in the illustrated papers in this country devoted to amateur photography. The printing and general productions of the "Annual" are of the best.

"TRICK Photography." A sixpenny book which should "go" has been published by Messrs. Marshall, Brookes, and Chalkley, Limited, under the above title. It describes the many pleasantries which may be perpetrated and the variety of amusing effects which can be obtained by photography. These include the magic photographs, doubles, photographic caricatures, wide angle effects, distorted portraits, and the many forms of combination printing. The many illustrations are a feature. We are glad to see that the author, in speaking of trick photographs by means of sulphate of

quinine, points out that the wet-plate process should be used. The caution is frequently omitted by writers on the subject.

The Christmas number of the "Weekly Press," Christchurch, New Zealand, has reached our table in time for us to lay it side by side with the numbers of London weeklies, in comparison with which it makes a very good showing. The half-tone work is excellent, and the colour printing of a kind which puts many an English printer to shame.

## New Apparatus, &c.

The Straight-Edge Lantern-Slide Printing Frame. Sold by W. Butcher and Son, Camera House, Farringdon Avenue, London, E.C.

Lantern-slide making by contact calls, as every slide-maker knows, for a special frame, or the work of printing from a set of mixed negatives becomes tedious in the extreme. Hence the variety of

printing frames for this purpose in the market. Messrs. Butcher nevertheless, in the instrument before us have gone one better than their predecessors in providing an additional convenience, and one which we judge lantern-slide makers will be very glad to have. In addition to allowing any portion of the negative—up to whole plate in size—to be used, and besides permitting the negative to be placed at an angle in the frame so as to compensate for skew-wise placing of the subject on the plate at the time of exposure, the makers give the slide maker the means of instantly seeing whether his slide will be correctly printed as regards the perpendicularity of the subject. This is done by the addition of a ruled screen, which is brought over the negative. The illustration shows it raised. The negative being seen to be correctly inserted, the lantern plate is placed in contact and the hinged back, seen on the left of the drawing, brought down upon it to press it into contact. Slide makers can obtain this frame from their dealers for 4s.

A PRINT-TRIMMER which is specially adapted for professional use is the Merrett, marketed by the Adhesive Dry Mounting Co., of 27 and 28, Fetter Lane, London, E.C. We have used many varieties of trimmers, but we know of none that will cut so cleanly and work with such uniformity as the Merrett. It will trim print wet or dry, and is made also in the larger sizes for working by treadle. The trimmer is not intended for cutting cards, but for prints, even those on a fairly heavy stock, it is an excellent instrument.

ROMANIAN Tariff.—Recently changes have been made in the duties on photographic materials imported into Roumania, and the following are the chief items:

Postcards, picture, photographic, etc.	per 100 kilos	200 lei.
Sensitive papers	" " "	50 "
Sensitive plates	" " "	20 "
Plates for cinematographs, optical lanterns, etc.	" " "	20 "
Optical glass, cut, polished, unmounted	" " "	150 "
Photographic apparatus	per 1 kilo	0.50 "

A lei is practically equal to a franc, and 25.50 go to the pound sterling.

PHOTOCHROM COMPANY.—Mr. E. Hagger has been appointed to the representative staff as London traveller for the process department.

## New Materials.

"Fixolene" (Lumière fixing salt). Sold by the Lumière N.A. Co., 4, Bloomsbury Street, London, W.C.

Under this title the Lumière firm has brought upon the market a fixing salt which is presumably on the lines of the investigations by M. Lumière which appeared in our pages some weeks ago. The commercial product is a white salt which dissolves in cold water to a pale green solution. This operation takes place very quickly, the solution not being appreciably chilled as in the case of making up a fixing bath from hypo. only. The chief feature of the bath, however, is its simultaneous fixing and hardening action, the very pronounced character of which will be obvious from the recital of the tests which have been made with the sample cartridge sent to us for notice. Two plates were fixed, one in the normal acid sulphite fixing bath and the other in a bath prepared with this new salt. The plates were then rinsed and part of each immersed in water at 100 deg. Fah.; that fixed in the normal bath was in five minutes practically melted, whilst the plate treated with this new bath showed no change. Further tests were then made with the plates fixed in the latter bath, and after five minutes' immersion in actual boiling water—that is, water boiling the whole time—gelatine seemed unaffected, except for having swollen somewhat. Another plate was then immersed in boiling water for five minutes and left in the same till the water was cold: this also seemed unaffected.

It is obvious from these tests that the new fixing salt will be of considerable practical value, for preliminary tests showed that there is no practical slowing of the actual operation of fixing, and the removal of the hypo. by subsequent treatment with hot water must be considerably hastened.

Agfa Fixing Salt. Sold by Charles Zimmermann and Co., 9 and 10, St. Mary-at-Hill, London, E.C.

The claims made by the makers of this new fixing salt are that it is more rapidly, and that it is not rendered appreciably slower by repeated use in the way that other fixing baths are. We are not able to confirm the first of these important claims, for we find on making up four-ounce per-pint baths of the Agfa fixer and of ordinary hypo, that the former completely removes the visible silver in a plate in one-half the time required by the latter. This was found, not in the case of one plate only, but in the course of fixing six half-plates successively in the same seven ounces of each bath. We found that the time of fixation did notably increase in the case of the plain hypo compared with the Agfa salt, though not in the proportion stated by the makers in the circular. We were not informed in the circular, however, what volume of solution was employed, say, for the fixation of ten half-plates, and therefore our own trials may not have reached the degree of exhaustion which is necessary before a comparative test becomes of any value. Yet the fact is clear to us that the bath is very rapid fixer, and as it is made in a few moments and preserves its clearness in use it should be a very satisfactory form of hypo, particularly for the use of amateurs who are apt to go wrong in commanding an acid fixing bath.

The fixing salt is sold in tins in three sizes, sufficient for baths of 5 ozs., 31 ozs., and 75 ozs. respectively, the price of the tins for these solutions being 5d., 9d., and 1s. 4d. It is also marketed in cartridges to make 3½ ozs. of bath sufficient to fix 25 quarter-plate negatives. The price of ten cartridges is 2s. 3d.

Cadett "Royal Standard" Ortho' Plates. Made by Cadett and Neall, Ashstead, Surrey.

Messrs. Cadett and Neall, who for many years past have been manufacturers of colour-sensitive plates, have of late applied themselves more to plates of medium colour-sensitiveness than to those of extreme red-sensitiveness such as the "Spectrum." This policy—which is no doubt the natural result of the greater demand for a plate which can be worked in a reasonably comfortable red light—has led them now to bring out an orthochromatic variety of the popular "Royal Standard," the properties of which bear out the old opinions formed of its "ordinary" predecessor. The "Royal Standard Ortho" is a liberally coated plate of good speed and "dear" characteristics in development. Like all plates of its degree of colour-sensitiveness, a light filter is necessary to take advantage of its properties under ordinary conditions, and one in-

creasing the exposure five or six times will be found to give a very good rendering of subjects in which reds do not occur. We have no fault to find with the new plate in regard to its mechanical properties of evenness of coating. The sample sent to us is on thinner glass than usually used for negative plates, and the film of emulsion exhibits the signs of the most careful manufacture.

In continuance of our usual practice, we give also the results of sensitometer in tests now made for us by S. E. Sheppard, D.Sc., F.C.S.,\* which are as follows:—

Inertia (pyro-soda H. and D.), .254.

$\gamma$  (density-giving power of the plate), 1.76.

K (velocity constant of development with standard ferrous oxalate), .120.

$t_{\gamma}$  (time in minutes to reach a standard development factor of 1), 7.0.

Blue sensitiveness  
× = Yellow sensitiveness, 13.2.

These figures, on reference to former articles on sensitometric valuation of plates which have appeared in the *BRITISH JOURNAL*, and are epitomised in the "Almanac," show the "Royal Standard Ortho" to be a plate of the erythrosine type, with a tendency to softness in the negatives and a time of development which is also an average one. In other words, anyone taking up the new plates will find his routine need not be disturbed in order to obtain the orthochromatic effects which the plates give.

## Commercial & Legal Intelligence.

CANASSER SENTENCED. Edward Smith, a canvasser, was charged last week at Marlborough Street, W., with being a suspected person, found on premises at 3, St. Alban's Road, Highgate, supposed for a felonious purpose. The evidence showed that about 12.30 on Saturday morning Mr. Goodison's son saw the prisoner come out of a lumber room, descend the staircase, and walk out of the house. Police-constable 247 Y, into whose custody the prisoner was given, found on him a book of coupons for photographs. Those coupons were for sale at 3s. each, the balance to be paid subsequently. Detective Page made inquiry, and found that the firm—Messrs. Lintott, photographers, of Bond Street—to whom the coupons referred, had ceased to exist for the past two months. In his defence the prisoner said he had worked for that firm as a canvasser up to two months ago. Lately he had been hard up, and was induced through want to try and sell some of the coupons for 3s., but had not sold any. The prisoner's character was disclosed by Detective Page, who said that Smith was sentenced in 1899 to twelve months' imprisonment, after previous convictions. Mr. Page sentenced the prisoner to two months' imprisonment.

ALLEGED CANVASSING FRAUD.—Charles King, apparently a man of good education, was committed for trial by the Manchester City Stipendiary last week on three charges of obtaining money by false pretences. According to the evidence, the prisoner called at three shops, representing that he was a canvasser employed by Messrs. Brown, Barnes, and Bell, photographers, of Victoria Street. In each instance, it was alleged, he called at small shops and offered enlargements of photographs at cheap rates on condition that part of the money was paid down, and that the photographs were displayed in the shops for a week as an advertisement. He received three sums of 2s. 6d., 5s. 6d., and 2s. 6d. King had called at the photographers and was supplied with the ordinary printed matter and receipts for canvassers, but he never took them any orders or went to their premises again. When charged with the offences prisoner replied, "I have collected some of them."

SMASHED NEGATIVES. At Greenwich Police Court, last week, R. W. Burge and J. Keene, inventor, of Belmont Hill, Lee, were charged with damaging a number of photographic negatives at 17b, Empire Road, Sydenham, Burge being also charged with assaulting Albert Ashby. Ashby who is manager of a photographic studio, stated that the prisoners, with a sailor and another man, called there on Saturday and said they wanted their photographs taken. Seeing

Mr. Sheppard has made these tests for the "British Journal" since Mr C. E. K. Mees, D.Sc., joined the firm of Wratten & Wainwright.

they were in drink, he told them he was not taking photographs that afternoon. Keene at once smashed a number of negatives, while Burge swept several off the mantelshelf. When he tried to close the door, so as to keep them there until the police came, Burge struck him in the face. The damage amounted to about £2. The prisoners were each fined 10s. and 20s. damage, and for the assault Burge was bound over in £5 to keep the peace for three months.

**RAPID PHOTO. PRINTING COMPANY, LTD.** (London).—Issue on November 1 of £300 6 per cent. debentures, part of series created July 2, 1906, to secure £10,000, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. Total amount previously issued of same series, £6,300.

**W. H. HARRISON, LTD.** (Photographers, South Kensington).—A 5 per cent. debenture, dated November, 1906, to secure £500, charged on the company's undertaking and property, present and future, including uncalled capital (if any), has been registered. Holders: Peacock, Wilson, and Co., Lincoln.

#### NEW COMPANIES.

**VICKERS' MINIM PHOTO. PRINTER, LTD.**—Capital £1,000, in £1 shares. Objects: To acquire and deal with any interests in patents and inventions relating to improvements in photographic printing, developing, and drying apparatus, and to carry on the business of manufacturers of and dealers in such apparatus, etc. No initial public issue. The first directors are not named. Registered office, 822, Salisbury House, E.C.

**WALLACE AND GILBERT.**—This company has been registered with a capital of £5,000 in £1 shares (1,600 5 per cent. cumulative preference) to acquire the business carried on by J. W. Wallace and J. C. Gilbert at James Watt Street, Birmingham, as "Wallace and Gilbert," and to carry on the business of photographers, draughtsmen, designers, engravers, etchers, electro-typers, die sinkers, etc. The subscribers are J. F. Wallace, Mrs. A. Wallace, Miss E. M. Wigston, J. C. Gilbert, Mrs. A. M. Gilbert, J. S. Gilbert, and Miss A. D. Gilbert.

## News and Notes.

**ILFORD Platona Paper.**—In consequence of the increasing rise in the price of platinum the price of the Ilford Platona paper is raised to 1s. 8d. per tin of 20 quarter-plate pieces; other sizes in proportion. The 24 x 17 sheet will now be sold at 27s. per half quire, and the 26 x 20 sheet at 34s. per half quire. A circular of all the new prices may be obtained free from the Ilford Company.

**IMPROPER Photographs.**—A man, named Kumberg, trading at Kilburn as Wilson and Co., was charged last week with sending improper postcards through the post. Prisoner was committed for trial on bail of £200.

**NOTTINGHAM Exhibition.**—The Nottingham Camera Club has arranged with the Sheffield and Leicester exhibitions for photographs to travel free between the three shows. In addition to this inducement, the Nottingham Society will present awards to successful exhibitors in the shape of pictures purchased from the walls to the value of one guinea each. The last day for receiving entries is February 14. Entry form from Mr. G. R. Cranch, St. Jude's Avenue, Mapperley, Nottingham, and the judge is Mr. Furley Lewis.

The new Spanish banknotes have a fine steel-plate engraving back and front, with a special colour ground in specially chosen colours for the prevention of imitation by photograph, which is one of the most popular methods of forgery; in fact, nearly all banknote forgeries are photographic in origin; and the aim of the designer and engraver is to guard against this. The notes are of the value of 25, 50, and 100 pesetas respectively; each of the values contain a different picture in the way of vignettes, and each carries a different scheme of colour work; all of them are considerably smaller than the Bank of England notes.

Last week a fire occurred on the premises in Nethergate, occupied by Mr. J. T. Chisholm, photographer. The damage, which amounted to about £150, is covered by insurance. The origin of the fire is not known.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Dec.	Name of Society.	Subject.
7.....	Newton Heath Camera Club...	"Postcard Photography on 'Rotograph' and 'Rotox' Postcards."
7.....	West London Photo. Society...	"Enlarging by Artificial Light." F. Hart.
7.....	Cardiff Photo. Society .....	"Bruges." W. A. Meyrick and R. Harris.
7.....	Hampstead Scientific Society	"Weather and Weather Observing Illustrated." Hugh Robert M.D.Sc.
8.....	Aberdeen Photo. Art Club....	Lantern Evening.
10.....	Leek Photo. Society .....	Exhibition of Competition Prints.
10.....	Gravesend and Dis. Ph. Soc....	"Ozobrome." A. E. Swift.
10.....	South London Photo. Society	"Trimming and Mounting." W. Calverley.
10.....	Lancaster Photo. Society .....	Marshall, F.C.A.
10.....	Preston Camera Club .....	"The Growth of a Picture." J. Cranstrated, Miss Marsden.
10.....	Oxford Camera Club .....	Photography Prize Slides.
10.....	Muirkirk Amat. Photo. Assoc.	"Enlarging Simplified."
10.....	Oldham Equitable Ph. Soc....	"Pictures with the Goetz Lens."
10.....	Bedford Camera Club .....	"Sports and Pastimes with the Goetz Anschutz Folding Camera."
10.....	Derby Photo. Society .....	"Enlarging Simplified." J. J. Griffith & Sons.
10.....	Stone and District Photo. Soc.	"Enlarged Negative on 'Rotograph' Negative Paper."
11.....	Royal Photographic Society ...	"Thunder-storms and a Camera." W. J. S. Lockyer.
11.....	Glasgow Southern Pho. Assn.	Discussion.
11.....	Leeds Photographic Society...	"Lantern Slide Making." Demonstrated, Godfrey Bingley.
11.....	Hove Camera Club .....	"How to Mount and Frame Photographs." Col. W. L. Noverre.

13.....	Leek Photo. Society .....	"Relaying on 'Rotograph' Paper Demonstrated. Rotary Co."
13.....	Small Heath Photo. Society ...	"Leading Features of Velox Manipulation."
13.....	Leek and District Photo. Soc.	"Enlarged Negatives on 'Rotograph' Negative Paper."

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, December 4, Mr. E. J. Wall in the chair. A demonstration of three-colour portraiture and printing was to have been given by Mr. H. W. Lewis, of 8 James's Studio, but Mr. Lewis was unable to be present through

indisposition, and his place was taken at an hour's notice by Mr. W. A. Sims, of the Rotary Photographic Company. Mr. Sims described the method adopted for taking the three negatives in the studio, and proceeded to deal with the process of printing them on three-colour carbon films. He exhibited a number of specimens of a carbon three-colour print in various stages of manufacture, and demonstrated the completion of the trichrome by laying the red impression upon the yellow and blue.

A number of questions were asked. Mr. H. O'Farrell said he had not been able to develop his carbon films at the low temperature of 85 degrees recommended by the Rotary Photographic Company, but had to use 110 degrees. He sensitised his prints one day and printed them the next. Dr. Mees said he found it was essential to develop the prints within an hour or two of sensitising. In reply to a query by Mr. Hector Maclean, Dr. Mees said he had not stored the sensitised films in a calcium tube. In the course of other discussion, the chairman stated that he sensitised his films with a bichromate solution containing citric acid, as recommended by Mr. H. W. Bennett, making it just alkaline with ammonia. He found that the films could be used perfectly the day after sensitising without special precautions. In place of the hot gelatine solution, directed by the Rotary Company for cementing the prints, he kept a stock of cold solution of gelatine, made by dissolving the gelatine in glacial acetic acid and diluting the solution with alcohol.

A vote of thanks to the St. James's Studio and to Mr. Sims concluded the business of the evening.

**CROYDON CAMERA CLUB.**—Mr. H. W. Bennett, F.R.P.S., on the 22nd ult., read a paper, "Is Time Development Desirable?" an abstract of which, together with the discussion which followed, we publish next week. On the proposition of Mr. Dodsworth, seconded by Mr. J. M. Sellors, the club formally recorded and tendered its congratulations to Messrs. Mees and Sheppard on their becoming Doctors of Science for original work in photo-chemistry, and all, including the lecturer, informally, and with evident sincerity, expressed their gratification at the distinction gained. Mr. Sellors struck a true note when he said that the high regard they all had for Dr. Mees rose, not so much from the knowledge he possessed, but rather from the unassuming way in which he was ever ready to impart it to others. Dr. Sheppard they had not seen for a long time, but on his return from abroad they hoped this would be remedied.

**HARROW DISTRICT PHOTOGRAPHIC AND SCIENTIFIC SOCIETY.**—The above society has been formed, and the first meeting was held on Saturday last in the Harrow Technical School, when Mr. W. S. Cullen read a paper on "Gaslight Printing." Those in the district desirous of joining should approach the honorary secretary, Mr. Edmund A. Robins, "Newlyn," 86, Station Road, Wealdstone.

**SOUTHAMPTON CAMERA CLUB.**—On the 3rd inst. Mr. C. M. Cooper lectured to a good attendance on "Rochester and its Cathedral."

**DAGUERRE'S First Photograph.**—Mr W. Gardner, M.I.Mech.E., sends to the "Westminster Gazette," of November 29, an interesting note apropos of the statement made the other day that Lord Avebury was the first person photographed in England by Daguerre: "It might (he says) interest your readers to know that my uncle, Andrew Shanks, a well-known engineer in London a generation back, was personally acquainted with M. Daguerre, and visited him in Paris up to the time that he had invented his process for taking photographs. Up to that time M. Daguerre had never attempted to take portraits, but simply architectural subjects and landscapes. My uncle suggested to him that he ought also to apply it to portraiture. M. Daguerre replied that if he would sit down he would make his first experiment upon himself. This challenge my uncle accepted, and he sat for one hour in brilliant sunshine in order to have his portrait taken by the new process. This portrait is still in existence, and in possession of my mother, who had it given to her by my uncle." It is an undoubted fact, adds Mr. Gardner, that this is the first photograph ever taken by Daguerre under his patent process.

At the Optical Society, next Thursday, Dr. C. V. Drysdale is to read a paper on the "Evolution of Artificial Lighting." Visitors are admitted to the meeting, which is held at the society's rooms, 20, Hanover Square, W.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### SULPHIDE TONING.

To the Editors.

Gentlemen,—In reference to Mr. Carnegie's interesting article on "Sulphide Toning," it might be worth noting that excellent warm tones are obtainable if one "bleaches" with ferricyanide alone, omitting the bromide; the solution can be used as strong as 5 per cent., and the yellowish image makes its appearance in thirty to sixty seconds. With sixty seconds' "bleaching" quite a warm sepia tone is obtained on treatment with the sulphide solution. The bleached image is very much more visible also than when bromide is used with the ferricyanide.

Perhaps Mr. Carnegie could express an opinion as to whether the image bleached with ferricyanide alone consists of sub-bromide or only ferricyanide of silver.—I am, yours faithfully,

T. THORNE BAKER.

Chislewood, London, N.W.

December 1, 1906.

### WASHING POSTCARDS.

To the Editors.

Gentlemen,—In your issue of September 14 last, Mr. G. T. Harris gave an account of a practical washing procedure by which two gross of postcards could easily be washed in three-quarters of an hour single-handed. We have endeavoured to work his method, but find we take a much longer time than three-quarters of an hour, and we should be glad if Mr. Harris or yourself would be good enough to indicate where we have gone wrong.

As we understand the method, each card is separately and carefully drained as it leaves the hypo bath, and the cards are then passed, with careful draining, from one tray to another for about four changes of water, left soaking for ten minutes, squeezed, soaked again, passed through a second four waters, squeezed a second time, passed through a third four waters, squeezed a third time, and placed to dry. There are thus twelve waters, two soakings, and three squeezeings.

It appeared at first sight that in this process it was intended that each card should be drained singly twelve times. But we find that two dozen cards are the most that can be drained singly per minute, so that twelve minutes, at least, are occupied in each draining of the two gross. Allowing fifteen minutes for the two soakings, and ten minutes for the squeezeings, only twenty minutes remain for draining and transferring the cards, and it is evident that the process cannot be completed in three-quarters of an hour, even if each card is separately drained twice only, and the other ten transfers between washing waters are effected en masse. We doubt whether in this case the cards would be sufficiently washed.

I may add that the method I adopt for washing my (gaslight) postcards is to pin each to a cork and float it on a domestic bath, allowing one change of water for every three dozen cards. This method is rather slow, and possibly imperfect, and I should be grateful for any suggestion for improving on it.—I enclose my business card, and am, yours faithfully, A COUNTRY POSTCARD PRINTER.

### THE UNITED STEREOSCOPIC SOCIETY.

To the Editors.

Gentlemen,—I am aware your journal takes great interest in stereoscopy, hence I wonder that it never mentions any of the proceedings of a society called the United Stereoscopic Society. A. J. Snow, hon. secretary, 74, Lloyd's Road, Walthamstow, L. There are about forty members, and the work is exclusively stereoscopic. Every month a set of about thirty slides, supplied by members, circulates amongst them, with criticism sheets. There is also a regular intercourse and improvement in the work done. Eventual exchanges are also made. Further, in November every year, there is a competition amongst the members, which is judged by themselves,

everyone sending to the secretary the name of the slides he selects as best.

I have been one of the members for the last three years, and this November competition set has just been sent in to me for examination, and I re-forwarded it to one of our members in England. This competition set is composed of 128 slides, all in normal size, prints on paper, mounted on boards.

I am the only Continental member, and it is singular that on this side of the Channel it has proved so difficult to establish stereo-clubs. The only one that has been in existence since 1904 is the Stereo Club Français, at Paris, but no circulation of slides nor criticism have been started up to the present. The English stereo society is therefore somewhat a pioneer, and hence the more worthy of notice.—I am, dear Sirs, yours sincerely,

VICTOR SELB.

42, Rue des Drapiers, Bruxelles.

November 30, 1906.

### THE STABILITY OF PYRO-SODA DEVELOPING SOLUTIONS.

To the Editors.

Gentlemen,—Re your leader on "The Pyro-Soda Developer," in the B.J.P., of November 23, I regret I omitted to mention temperature at time of development. Finding that platinotype printing requires a negative as full of gradation as possible, and yet of sufficient contrast to give an artistic result, I experimented with several formulæ with 1, 1½, and 2 grs. of pyro to each ounce of developer, using sufficient developer to ensure each 4-plate receiving two grains of pyro.

So far, I find the most pleasing results follow the 1½ gr. pyro per ounce, with a factor of twelve without potass bromide, or a factor of six if included. Consequently I was much interested in the three formulæ published in your issue of November 2.

The following is the exact order of mixing:—Temperature 62 deg. F. Time of first appearance: Formulæ A and C, 45 secs.; factor 12: 9 mins.; formulæ B, 90 secs.; factor 6: 9 mins. Equal parts I. and II.

A.		
I.—Soda sulphite .....	33	grs.
Potass metabisulphite .....	8	grs.
Water to .....	2	ozs.
Pyraze .....	6	grs.
II.—Soda carb. ....	66	grs.
Water .....	2	ozs.
B.		
I.—Soda sulphite .....	48	grs.
Potass metabisulphite .....	3	grs.
Water to .....	2	ozs.
Pyraze .....	6	grs.
II.—Soda carb. ....	48	grs.
Pot. bromide .....	14	grs.
Water to .....	2	ozs.
C.		
I.—Soda sulphite .....	36	grs.
Potass metabisulphite .....	6	grs.
Water to .....	2	ozs.
Pyraze .....	6	grs.
II.—Soda carb. ....	72	grs.
Water to .....	2	ozs.

—Yours very truly,

Woking. November 25, 1906.

CLAUDE DE NEUVILLE.

[We are much obliged to M. de Neuville for the information contained in his letter. Our conjecture that he made up all three formulæ in the same way is correct, hence it is not surprising that the results were so similar. His experiments seem to prove that the excess of metabisulphite in A will not account for our experiences. We omitted to mention in our note on page 922 that all M. de Neuville's negatives show a greenish stain in the sky portion. This is contrary to our experience with A formula, which in our hands invariably gives absolutely stainless results. This may perhaps be peculiar to the ortho plates used by our correspondent, but it rather suggests a poor quality sulphite, and this again would account for the fact that the action of A in M. de Neuville's hands is decidedly quicker than in ours. Nine minutes at 62 degrees would, we believe (from experience with similar formulæ), be rather too long with B if made up in the manner adopted by Mr. Bennett. We have, how-

ever, not actually tested B, and the idea that the speed of a developer can vary simply with the order in which the ingredients are put together is too revolutionary to be accepted without careful experiment. Up to the present we are only prepared to assert that mode of mixing certainly affects the keeping qualities and cleanliness of the developer, and that on this account the sulphite should not be with the alkali.—Eds. B.J.P.]

### DR. LEHMANN'S WORK ON LIPPMANN COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—You would please me very much by allowing me to say, in reference to Mr. E. J. Wall's article (in your issue of November), "A Treatise on Lippmann-Colour Photography," that the is on page 947 a serious confusion in Mr. Wall's statement in the last but one paragraph of the named article.

Mr. Wall condemns Dr. Lehmann's diagram, reproduced as Fig. on page 946, as not correct, because, when the rays cross, the . . . is no light."

The error is, that Mr. Wall confounds the real crossing of light-rays of a different phase of oscillation—which causes darkness—and the mere symbolical, geometrical crossing of light-waves in the diagram above named. Such a diagram will be treated only accordingly to the laws of geometry: the upper curve is a mere geometrical construction, and shows the result of the lower ones, obtained in any way, known to all students of physics. The darkness in the upper curve at the end of the maxima is not caused by crossing of the rays, but by the circumstance, that there the lower waves both are at the zero-point; the little maxima following in the upper curve on the extreme right of the diagram, are not in contradiction with the crossing, but wholly proved by the—though small—positive sum of the opposed oscillations of the lower curves.—Yours faithfully

C. W. CZAPKA.

### THE CANVASSING TRADE.

To the Editors.

Gentlemen,—I was more than delighted to read in your column the letter signed "W. Doust," giving experience and how he was able to rout these gangs (nothing else) that infest not only England but Scotland, and they seem to thrive and grow fat on the credulity of the British public. It is not my intention, however, to explain or enlarge on their modus operandi, but, rather, to get at the root and give my experience at the fountain head. I may say I am a photographer of twenty years' experience in best studios, but I am another line now. Seeing, however, an advertisement in a Glasgow contemporary for a photographer, all-round man (alive), no duffers salary (mark the word) and half-profits, apply so and so, I went and saw my gentleman in a cosy armchair, with a rare fire and a snug. There were in outer office five men, two boys, and three girls all doing nothing inside the counter, and busy at it. I stated my business and was asked to be seated. I was then questioned as to my ability, which I answered by showing my references, which were evidently good, for he offered me a cigar and we got quite "pally." He then explained the business. Briefly, a studio at present shut, but having a lot of arrears (orders), he wished to complete to save proceedings. What did he mean? I was to do the work, which was considerable. When finished I was to share (not before), as he had to pay the gangs, rent, taxes, etc., etc., and in return, I was to get 10s. per week. I said, "per day?"—but he said, "No, per week!" Would you believe it? And he had a dozen applicants, so he said I was struck dumb, but looked as if I was willing. "There is a lot of money in this business, and I will make you my partner," was the next bait, "as I have a lot of irons in the fire." What was I to do? I sat on, and then it came out. "Outside are some of my canvassers waiting to go on. Would I fix?" Still I hesitated. They get 2s. 6d. per order. You copy photograph I get, 20 x 16, on stretcher for tenpence, then a little India ink to touch up; frame 3s. 3d. glass and back 9d., and there you are—7s. 4d.; add 4d. for negative and 6d. to the artist—in all, 8s. 2d.; and he charges 17s. 6d., and gets lots. I saw a pile three feet thick. A profit of 9s. 4d. is not bad, and yet he gets a lot to do. The office is in a principal street, and he goes under the name of \*\*\*\*\* I rose, gathered my own, and departed declining.

A BRILLIANT OFFER.

## PHOTOGRAPHERS, ASSISTANTS, AND CANVASSERS.

To the Editors.

Gentlemen,—Before again writing respecting the above heading, perhaps a few words of thanks will be appreciated by those photographers who have sent me letters of congratulation. Also, I thank particularly those who have so kindly offered to assist me in any scheme which I wish to bring forward; also to those assistants who have voluntarily sent in their names for the purpose of starting a society to work in conjunction with the P.P.A. to their advantage. The last few months a number of us have been trying to form some scheme whereby the assistants can gather a better knowledge generally from professional standing, and have intercourse with the best talent in the country. I should say, judging by the correspondence I have received, there is certainly a great opening for the same. After careful consideration, we have come to the conclusion that a union of the principles of most unions in the country is unworkable, owing to unfair competition, the bad state of the trade, also the general jealousy which exists amongst the assistants generally, and the variations of the different classes of work in photography. Until things are altered to a sound basis, by becoming efficient in the art, this state of things must always exist. I wish to point out to the assistants who have written to me (both male and female), to please refrain from sending me specimens of their work; also, I am not prepared to prescribe a remedy for their individual complaints. What I am going to do is to start a society for the ultimate benefit of all. So please note after this I am open for suggestions only, as the other makes me up with unnecessary correspondence.

Photography.—Perhaps no business lends itself so easily to fraud as that of photography. After the recent discussions in the JOURNAL of several of the leading local newspapers in the country, I have come to the conclusion that perhaps a little sidelight on the subject will convince the members of the profession generally. Since the articles quoted in the JOURNAL, also my letter of last week's issue, I have had several interesting letters from and chats with members of the profession who have made it their business to call. Also two canvassers called personally, and I assure my readers it was a pleasure to meet such men face to face and thoroughly discuss the principles of the trade. After carefully arguing the points at stake, we certainly came to the conclusion that the present methods of business require revising. Even the canvassers admitted that the methods were not worthy above suspicion. The photographers who employ these men, therefore, to side over a great many complaints against them, also to be very forgiving to them, or else to be continually engaging canvassers, which method is not always to the advantage of the business. Then to be continually forgiving, these men become familiar, and then familiarity breeds contempt, and they ultimately do as they think fit. After having passed through two or three of these establishments myself, I made a strong resolution that should I ever stand in a position which enabled me to say my say and to be heard with any credence, I would strongly advocate the demoralisation of these methods. At the same time I should aim at bringing employer and employee into closer union with each other. The opportunity has now come, and I intend to take the utmost advantage of that opportunity, after years of struggle to maintain the end. What I intend to advocate on behalf of employers and assistants, "both male and female," I place under two headings.

**For Employers.**—In the first instance, when advertising for assistants, etc., he should certainly state whether he is doing "cheap canvassing" work or not. The assistant who is travelling from a distance then would exactly know what he is going to, as in many cases on arriving he finds he has been completely duped, and after a short stay to recover himself, is compelled to return home, to be unemployed perhaps for a considerable while, after missing a good opportunity in order to take up what he thought to be a better one. If he finds himself compelled to stay at this establishment, perhaps owing to not having a home to go back to (and in my career I have known such cases), he is perhaps ruining his prospects of a brilliant and prosperous career. Who is to blame but the employer? If the advertiser would kindly note this when advertising, by placing in advertisement "no canvassing," they will be doing a great kindness to assistants generally.

**For Assistants.**—In many instances they apply for situations which cannot possibly fill owing to being incompetent. On arrival at the establishment that has engaged them, the head of the establishment (either

proprietor or manager), finds they are quite incompetent to undertake the work, but keeps them on solely as an act of generosity until they are landed into another situation, and a sigh of relief is heaved by employer when at last they have departed to fields anew. I am not going to mince matters, but tell you straight, whether I offend or please, that you are more or less to blame for this state of things, through not having a proper organisation. Before anything can be done you must recognise a parent society, and that parent society must in all cases consist of the best talent in the land; therefore, we must look to the P.P.A. for that help, as no other society exists which can undertake such things. We are not going to discuss merits, we having had enough pessimism before; we must be straight to the point, and sharp about it; so I will deal in my next paragraph as to the methods of obtaining the desired end.

All those assistants, both male and female, of all the different branches of photography, who are willing to become members of a Photographic Assistants' Protective Society will kindly send their full names and addresses to me. I shall be very pleased to receive the same. Any suggestions will be warmly welcomed, and will enable one to form some idea as to what the assistants require. To make the society a success it requires a great number to be added to the existing fifty-four who have offered to assist me. No fee is asked, and all costs are being borne by me until some idea is gathered as to whether photographic assistants generally are in one accord with the idea of improving matters generally. When I have gathered in all members, or, at least, intending members, the general numbers, also practical suggestions, will be sent to the JOURNAL. So I hope all assistants will take in the JOURNAL to watch over coming events, and to let me have from time to time practical suggestions that might occur to one. Now, when I have placed all suggestions in order, and got everything in working order, I intend to kindly ask the P.P.A. to meet me to discuss the matter, and I hope they will extend the hand of welcome, however humble one's cause might be. I have no doubt this opportunity will be taken by them, and then, perhaps, a lasting and most beneficial society will be formed, and always in one accord with each other. Rules so far suggested:

1. That a book of names be kept of all the photographic firms in England, Scotland, Wales, and Ireland, the object being for the use of assistants when applying for situations, the said book giving their names and standing.
2. To be amalgamated with the P.P.A. to aid in gaining better facilities for passing examinations.
3. To have a correspondence bureau direct with the P.P.A. on all matters pertaining to assistants.
4. To pay an annual subscription to the P.P.A. to aid in these matters.

Also, that we petition the P.P.A. to supply suitable books for professionals only, at a nominal charge, to aid in the different courses of examinations.

Now, I have had my say, and nobody can say I have not tried to make matters brighter, and if I go under through the assistants being afraid to rally, then I go under knowing I have tried my best.

Will the assistant please note that it is very costly to reply to letters, etc. All I want is intending members and suggestions, so I have decided not to reply unnecessarily, as my time is fully occupied at present with other correspondence.—Believe me, your servant at all times.

W. DOUST.

19, Richmond Terrace, Romsey, Hants.

MESSRS. WINDOW AND GROVE have removed to 58, Westbourne Grove from 63, Baker Street, the premises where their business has been carried on for the past fifty years.

It is announced that the first exhibition at the International Art Gallery, consisting of works by modern British, French, and Dutch artists, will be held at 14, King William Street, Trafalgar Square, from December 12 till January 5.

Those interested in cinematographic and lantern work should write to The Service Company, Ltd., 292 and 293, High Holborn, for a card of invitation to their lantern and cinematographic display, which will be given on Tuesday evening, December 11, from 7 to 8.30 p.m. This company is also giving talking machine and pianola recitals every Monday, Wednesday, and Friday, from 1.30 to 3 o'clock, and will be pleased to welcome all who are interested.

## Answers to Correspondents.

- \* \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* \* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* \* \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- \* \* \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- J. W. Agar, Gildersome Street, Gildersome, near Leeds. *Photograph Titled: "It's Done at all Ages."*
- R. Thirlwell, 21, Bridge Road, Stockton-on-Tees. *Two Photographs of Mr. Geo. Butterfield.*

**DRY COLLODION PLATES.**—I should be glad if you could inform me if there is a dry collodion plate made for process work, so that instead of using a wet plate one could use a dry plate. If you would kindly reply through your paper.—COLLODION.

So far as we are aware there are no dry collodion plates, made commercially, at the present time. Messrs. Penrose and Co., Farringdon Road, E.C., supply a collodion emulsion with which you could make your own dry plates with little trouble. Possibly Mr. Wm. Brooks, of Reigate, might make you some collodion dry plates to order. You might communicate with him.

**LICENCE FOR STILL.**—Could you tell me if it is necessary to have a licence to redistil alcohol used in photograph—and if so, how much would it cost?—T. A. KEYSER.

The cost of a licence to use a still is 10s. per annum. You can get it by applying to the Excise Department at Somerset House. With the licence you will not be allowed to tamper with methylated spirit with the view to purifying or deodorising it. If you require unmethylated alcohol for photographic purposes, the usual kind as supplied by such houses as Hopkins and Williams, and others, is all that is required. With that there would be no necessity to redistill.

**VALUE OF PAINTING.**—Kindly let me know what the value would be for a picture of the Madonna and Child, by Gustave Doré, size 36 by 28, in a good state.—T. M. K.

Out of our province. Your best course is to send the painting to an expert, e.g., Mr. Augustin Rischgitz, Linden Gardens, Bayswater.

**LENS QUERY.**—I have to make some full-length figure studies and small groups (quarter and half plate negatives), and the farthest I can get camera from figures is about 20 ft (the space distance being really 22 ft. 6 in.). To do this work what is the best kind of lens? Would an Optimus 1/1 plate Rectilinear do; or a Busch No. 3 Aplanat? Kindly advise me.—RURR.

For taking groups at this time of year we should advise you to employ a portrait lens above all others. For the half-plates we should recommend a lens of about 11 in. focus. Such a lens requires about 18 ft. between camera and sitter for a full-length cabinet picture. But the space at your disposal will not permit of such a lens being used for the quarter-plate size. For that you will require one of about 8 in. focus. This lens, however, would do for the larger-sized groups.

**COPYRIGHT.**—Will you kindly answer the following:—I have a 1d. coloured picture some ten years, with no name or number on, and I have succeeded in finding out the last publisher, and I am informed it is out of print, and they are unable to give me any information. Could you favour me by letting me know how I may find out if the design is copyright or not? If copyright, should it not bear name or number? As I wish to

reproduce it for postcards any information will be a great help.—REPRODUCTION.

The copyright in a picture lasts for the life of the artist and for seven years after his death. The only way to find out whether there is any copyright in the picture is to ascertain who is the artist, and whether he is living, and if not, how long he has been dead. It is not at all necessary that a copyright picture should bear the word "Copyright," nor need it bear a number.

**CHARGES FOR PHOTOGRAPHY.**—I would thank you to give me your opinion whether the following charge is a moderate price otherwise for a professional photographer who considers he knows his work and can do it:—Taking two 12 by 10 negatives, two positions, of a flour mill, and supplying a print each of same, 15s.; two negatives (one each of lakehouse and biscuit factory, and supplying print each, 10s.; two half-plate size buildings from two separate negatives, 5s.; total, 30s. Your opinion will oblige.—W. J. B.

Very moderate indeed for first-rate work.

**J. LOCKWOOD.**—Get a book of instructions issued by Jonathan Fallowfield, 146, Charing Cross Road, London, W.C.

**A. D. (Le Llex Frame).**—Shellac is "laque," "gomme laque," "résine laque." Japanner's gold size is a solution of copal and other resins in boiled linseed oil and turpentine. We do not know its French name.

**POSTCARD.**—I. Get a copy of the "Picture Postcard" (The Postcard Publishing Co., Imperial Building—Ludgate Hill, E.C.). Usually half-plate prints.

**F. F.**—Try W. Griggs, 20A, Old Town, Clapham; Wertherman & Co., Enfield; Waterlow and Sons, Ltd., London Wall; Morgan and Kidd, Richmond.

**RETOUCHING AND PLATINOTYPES.**—We have never met personally with the trouble, but have heard of it. We should say that probably some damp was locked in the film, owing to the semi-impermeable coating of the medium, and when the paper was brought into contact was locally absorbed. If the medium was capable of absorbing or in any way condensing moisture the same result would follow, but this does not seem likely. Careful drying the negative would probably obviate the trouble, but we warn you against bringing platinotype paper into contact with a hot negative. We do not see how the medium *per se* would affect the paper, but retouching will sometimes give black spots possibly due to the lead or the tackiness causing dirt to adhere.

**COLOUR PHOTOGRAPHY.**—Will you kindly inform me, with reference to B.J.A., for 1907 (1) page 648, what fixing agent is used for Worel's process? (2) Page 849. What is the angle of the "prism of small angle"?—E. Y. E. N.

(1) Benzine. A special fixing bath is made by Dr. J. H. Smith and Co., of Zurich (British agents, Oliver S. Dawson, 254A, High Holborn, London, W.C.). (2) The angle of the small prism is absolutely dependent on the width of the black line, or, rather its shadow, and must be such that the spectrum just fills the black shadow without overlap. In the B.J. for November 1906, p. 905, M. Cheron advises a prism of 12 degrees.

W. G. W. (Lancaster).—O. Sichel and Co.

\* \* \* **NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Time development.—An animated evening at the Croydon Camera Club was spent in hearing and discussing a paper on this subject by Mr. H. W. Bennett. (P. 985.)

Photography by electric wire.—The name "electro-photography" is suggested for the description of the processes such as have been before the public for the last few weeks. We give a short account of the latest intelligence as to the discoveries of Professor Korn and M. Belin. (Pp. 982 and 984.)

We refer again to the advantages of calculating in terms of extra-focal distances. For many purposes the use of extra-focal distances simplifies ordinary optical computations. (P. 982.)

Among other patents of the week are those for making invisible photographs which become spontaneously visible, metalline prints, and focussing view-finders. (P. 992.)

The first portion of a paper on timing the speed of shutters by M. J. de Graaf Hunter, of the National Physical Laboratory, appears on page 987.

The Southampton Camera Club has held a very successful exhibition this week at the Philharmonic Hall. The exhibition, which closes to-morrow, Saturday, is reviewed on page 990.

We continue to hear reports of the peripatetic fraudulent canvassers, and of the means effectually taken, with the aid of the local Press, to drive them from their prey. (P. 998.)

A case in the courts last week showed the profit which the makers of cheap enlargements expect to make. (P. 995.)

The tidiness of the studio is a matter which many professional photographers disregard—to the disadvantage of their businesses. (P. 983.)

## EX CATHEDRA.

### The Metric System.

At the ordinary meeting of the Society of Arts last week there was a grand discussion on the question of the metric system, which was introduced by Sir Chas. Watson in a paper entitled "Some Objections to the Compulsory Introduction of the Metric System." The old arguments as to the basis of the metric system being wrong by about one-five-thousandth, etc., were advanced, and, justly we think, shown as of no practical value in depreciation of the system, which gives us the much simpler division or multiplication by ten, than that which adherents of the duodecimal system support. It is perfectly immaterial whether the unit on which a given system be founded is correct or incorrect, as long as one can reproduce at will the accepted unit, and this is certainly the case with the standard metre, which can be at once re-established, were all the standard metres lost, through Michelson's measurements of the wave length of certain sodium and cadmium rays. The argument that English manufacturers would reap a benefit by the adoption of the metric system was met by the lecturer by a series of statistics that went to prove that the number of the inhabitants of Great Britain and dependencies and the U.S.A. who practically use our English system was greater than those who use the metric system; therefore, on the principle of might makes right, the rest of the world should adopt our system. Great Britain's dependencies include the Hottentots of South Africa, the Bantees, pigmies, etc., of Central Africa, and the aborigines of Australia.

### Photo-graphers and the Metric System.

Putting on one side, however, these facts, there is not the slightest doubt as to the great advantages of the adoption by photographers of the metric system of weights and measures, as regards formulæ. It is now almost an impossibility to tell what is meant in a formula, whether avoirdupois or the old apothecaries weight, or can one so readily compare formulæ when written in the English style as when in the metric. Many formulæ are now given, which, when reduced to percentages or parts per thousand, are so much alike as to be in practice the same, yet such is the glorious muddle of our system that a formula of old and tried worth has only to be juggled with by some writer, and it is at once hailed with acclamation and labelled with his name, although varying from what may have become a standard by minute fractions when reduced to percentages. It is hopeless to expect to force this or that system on to any large body of men, and it is only example which can induce them to adopt a system which is infinitely easier than their own, but which has the only demerits of being new.

### An Astronomical Trust.

The idea of a Trust in astronomical work, in the face of the prosecution of the Standard Oil Company in the United States, naturally at first sight gives one an uncomfortable feeling if science is to be cornered too; yet a Trust is actually proposed by Professor Pickering, of Harvard, his idea being not the accumulation of enormous fortunes—the one result of commercial Trusts—but the saving in expense, and greater output by which the colossal fortunes are made; but in this case these would be represented by accumulation of valuable information and detail, which is impossible under the present system. The basis of the proposed astronomical Trust is the foundation of a first-class observatory, equipped with, amongst other things, a 7-ft. aperture reflecting telescope, which should do nothing else but photograph the sky, whilst the plates or copies of them should be handed over to various workers all over the world for further use. Practically, Professor Pickering's idea is the founding of an observatory which should be devoted to the use of expert photographers, who should make negatives and positives, whilst astronomers should measure and discuss them. The hardest problem, Professor Pickering admits, would be to find an active committee with no taint of selfish dress—an article not unknown even amongst astronomers—who would be content to sink all ideas of gain of personal glory for the sake of the glory of science itself.

### The Front Principal Focus of a Lens.

We have shown how the rules relating to the extra-focal distances enable us to set up the apparatus for copying with the aid of the infinity mark alone. This infinity mark practically stands for, though it may not be in the place of, the back principal focus of the lens, and we dispense with the front principal focus by relying on focussing to secure a proper distance from lens to object. If, however, it is preferred to measure the second extra-focal distance, it is a simple matter to determine the front principal focus. Reverse the lens in its flange so that the hood is towards the focussing screen. Focus on a distant object and measure from focussing screen to lens hood or any convenient part of the lens that will serve as a datum. When the lens is in its normal position the dimension obtained in the test is added to the calculated extra-focal distance, and the total is then set out from the datum point fixed upon. There is no difficulty with the majority of cameras in reversing the lens on its flange, and in the few cases where this cannot be done a very little ingenuity will find an alternative. A temporary cardboard front into which the lens mount is screwed can be utilised in place of the proper front if the reversal of the lens is hindered by the presence of a "behind-lens" shutter. This simple method of finding the front principal focus is due to Mr. Dallmeyer, who utilised it in his method of determining focal length published in this journal on February 24, 1899.

\* \* \*

### The Measurement of Conjugates.

Recent correspondence on the subject of focussing scales has drawn attention to the fact that many workers still consider the nodes of the lens to be the points from which all conjugate distances should be calculated, measured, or set out. In a note on page 898 we pointed out some of the disadvantages attending this system, but as so few seem to be aware that there is any better system some further notes may be of use. As before stated, calculations are much simplified by measuring all distances from the principal foci of the lens, instead of from the nodes, for the rules connecting the extra-focal distances

are much simpler than those relating to nodal distances. First, the product of the two extra-focal distances is always equal to the square of the focal length, and is therefore a constant quantity for any particular lens. This means that the distances always vary in inverse proportion, so that when one distance is doubled or trebled, the other is halved or divided by three. This rule greatly facilitates the construction of focussing scales. Again, the extra-focal distance of the image is always equal to the focal length multiplied by the scale on which the subject is being enlarged or reduced. Thus, if we are enlarging twice (say  $\frac{1}{2}$  plate to 1-1 plate) the extra-focal distance of the image is two focal lengths, while if we are reducing to one-third full size, the distance is one-third of a focal length. If the enlargement or reduction is being made in a camera, in the one case the camera is racked out for two focal lengths beyond the infinity mark, and in the other for a third of a focal length beyond the same mark. The camera can then be bodily moved to and from the object until focus is secured. In daylight enlarging the camera takes the place of a lantern, and its extension represents the distance of the object, not that of the image. Under rule 1 the extra-focal extension will then be inversely proportional to the extra-focal distance of the image. In this case we rack out the camera for half a focal length beyond the infinity mark if we wish to enlarge twice, while we rack out three focal lengths beyond the infinity mark to reduce on a scale of one-third full size. Focus is then secured by adjusting the image screen. These methods of adjustment may easily give more accurate results than those based on nodal distances, for the exact position of the nodes is seldom known, and so the apparatus cannot be set up exactly by measurement alone. A final adjustment to secure focus is nearly always necessary, and generally this final touch upsets the scale of the image.

\* \* \*

### The Infinity Mark.

It is manifest that if the camera has been properly adjusted infinity mark, and we know the focal length, we can readily make any adjustment of the apparatus for copying on any definite scale without worrying over the so-called "law of conjugate foci." This law, though expressed by a fairly easy mathematical formula, is complex compared with the simple relationship of the extra-focal distances, and it cannot be applied correctly unless we know the exact position of the nodes of the lens, which are often nowhere near the assumed position. The infinity mark used must, however, be the true one, and not the so-called infinity mark of the average focussing scale. As we have before explained, the farthest distance shown on a focussing scale is usually the hyperfocal distance for the largest stop. It is often marked "infinity," but it is generally a considerable part of an inch beyond the true infinity mark, which is not on the scale at all. The true mark can be found within an accuracy of 1-500 in. by focussing sharply on any suitable object that is at a distance of more than 500 times the square of the focal length, and it is always advisable to ascertain it, as knowledge of its true position is at times invaluable. One can then, when copying to scale, always set out one conjugate exactly, and find the other by trial, while conversely one can at any time easily measure the extension beyond the infinity mark, and so ascertain the scale on which one is copying.

\* \* \*

### Seeing by Wire.

Following closely upon the announcements of Professor Korn's wonderful improvements in the electric transmission of photographs there comes a report of yet another and even more ambitious attempt to solve the gre-

problem of electrically transmitting images over a distance, the inventor hailing from France. M. Belin, of Nancy, whose portrait we give elsewhere, claims to have perfected a method, after ten years of work, whereby he is able to reproduce the image formed on the focussing screen of a camera at any distance from the transmitting station, and this over a single telegraph or telephone wire. He distinctly states, in some correspondence we have had with him, that he need not develop or print the image at the receiving station, that his apparatus is always ready for work, and that at the receiving end he can produce at will, and by the simple manipulation of a switch, either a positive or a negative record. Moreover, his system will produce photo-etched plates in a shorter time and more economically than has been possible hitherto. The inventor has been kind enough to promise us very shortly a photograph of the apparatus and some specimen results, and pending the receipt of these it would serve no purpose to comment further on the matter, save to say that if M. Belin is able to dispense at the transmitting station of the necessity of having a fixed record in the shape of a transparency such as all other systems of teleelectroscopy require, he has brought us appreciably nearer to the realisation of that hitherto utopian idea of electrically rendering visible at a distance living, animated scenes.

#### The Real Telephotography.

The advances of Professor Korn and M. Belin, which, from the accounts in this and previous issues of the *BRITISH JOURNAL*, are seen to be nearing the practical stage, have made a new word necessary. "Telephotography," or drawing from a distance, would certainly be that word, had not been appropriated for the use of a particular arrangement of lenses. "Photo-telegraphy" only suggests telegraphic communication by light; we want the inverse meaning conveyed into the word, viz.: photography along an electric circuit, and hence we are thrown back on such combinations as "Electro-telephotography," or "Telephoto-telephotography." Can anybody suggest a better name for the subject than the last?

#### THE APPEARANCE OF THE STUDIO, AND ITS EFFECT ON SITTERS.

Last week we referred to the reception-room as being, from a business point of view, the most important part of the establishment and to the effect that first impressions frequently have on prospective customers. Next to the reception-room is, or should be, the studio in which the portraits are taken. It is often the case that the excellent impression of the establishment and of the work produced which is created in the reception-room is considerably discounted when the sitter enters the studio where the portrait is to be taken. The former may be a picture of neatness, with everything in the best of order, while in the latter things are just the reverse. Here the sitter, if of an observant nature—and most persons are so, more or less—may have some misgivings as to whether pictures such as are shown in the reception-room are possible of production in such a place and amid such surroundings. Confidence in this case will at once be shaken and this may have its effect on the expression of the sitter. It is true that people who frequently have their portraits taken have become somewhat accustomed to this kind of thing, but that is not so with those who but seldom patronise photographers. With those, first impressions often go a long way. Even with the more accustomed ones, if they were introduced into a studio where all was unusually "spick and span," they could

not but be favourably impressed, and have additional confidence in the work to be done.

During the past year we have visited many photographic establishments in London, as well as in different parts of the country, and we must say that in the majority of them the studio has been the most slovenly and untidy place on the premises that sitters are likely to see. Our remarks on this point are not confined to what may be termed middle or lower-class businesses, but apply to some that may be classed much beyond those. One of the prominent things that has attracted our attention has been dirty and stained blinds and curtains. We all admit the difficulty there is in keeping the glass roofs of studios waterproof, and also that the water which gets through stains the curtains or blinds beneath, but the sitters, of course, do not realise this, and not unnaturally conclude that the place is neglected, as such a state of things would not be tolerated for a single day in their own homes. The blinds would be sent to the laundry, and why should not the blinds of a studio be dealt with in the same way when they become dirty? Everyone is fully aware that blinds on rollers do not run so well after being washed as they did when new; but now roller blinds, for the roof, are an exception rather than the rule. They have generally been superseded by short curtains running horizontally on wires or rods, and hang loose and baggy; therefore they will hang just as well after being washed as they did when first new. There is no reason why there should not be a duplicate set, so that a change could be made as soon as those in use became stained. The cost would not be great, as the material now generally used is very inexpensive. In this way, unsightly blinds could easily be avoided, and a more cleanly appearance given to the studio generally.

Another thing that has forcibly struck us in most studios is the general slovenly and untidy state of the place, conveying rather the idea of a lumber room than a studio in which artistic pictures are produced. Often it is loaded up with out-of-date backgrounds, which are damaged and out of use, as well as dilapidated accessories that cannot be moved without some portion falling off. These, even when new, are not, by reason of their sombre colours, very elegant things, but they are far less so when they are in a dilapidated or dirty condition. More than once we have been told that they helped to fill up and make the place look better furnished. We took a different view of the subject, and not a favourable one—an empty space is preferable to one blocked up with shabby-looking or dirty rubbish, for rubbish it is if the things are never used.

Faded, worn, and sometimes dirty carpets and rugs are frequently a great eyesore. It is quite true that the things may, and do, look all right in the finished pictures; but when sitters are invited to pose on them they cannot but fail to notice their state, which is very different from what they would endure in their own houses. Grass mats we have seen in use that were in a most deplorable condition, the greater part of the grass having disappeared long ago. All this sort of thing in a studio tends to misgivings as to the quality of the work.

There is another thing we have frequently noticed that seems to be much neglected by many photographers, namely, the appearance of the apparatus. Frequently the camera stands are devoid of polish, and the cameras in a similar condition, while the lenses, through long use, are conspicuous by an absence of lacquer, and very likely the hoods are more or less out of shape. Now apparatus in this state may, indeed does, produce as good results as it did when first new, but sitters may not have the same confidence in it as if it had a newer and

brighter appearance. A coat of French polish on the camera and stands, and the relacquering of the lenses, would make the apparatus look equal to new, and its appearance would not pass unnoticed by sitters. The unsightly matters we have called attention to are, probably, not so palpable to the photographer who is daily

working in the studio as they are to customers, particularly on the first visit. With them, the impression created by the well-appointed reception-room, and the excellent work exhibited therein, may be largely dissipated when they enter a studio of the character so frequently met with.

## TELECTRO - PHOTOGRAPHY.

In our issues for July 7 and 14 last year, a full description, with illustrations, was given of Professor Korn's process of sending photographs by wire. He has, however, since then made some important advances in his apparatus, which have resulted in considerable improvements in the results attained, as will be seen by the illustrations herewith.

tion of the galvanometer does not take place exactly with the same speed as the changes in illumination, and a quick change of illumination is felt in the galvanometer before the recovery of the receiving cell, so that details are recorded which would not otherwise be seen.

The practical application of this is that the troublesome

H.I.M. Kaiser Wilhelm.

Professor Korn.

H.H. The Crown Prince of Germany.

REPRODUCTIONS OF TELEGRAPHED PHOTOGRAPHS SENT BY PROFESSOR A. M. KORN FROM MUNICH TO NURNBERG.

The advance is, we believe, due to the fact that by a simple arrangement Professor Korn has been able to overcome the sluggish inertia of the selenium cells, for in a paper read before the Académie des Sciences (Comptes Rendus, December 3, 1907) he describes his method of effecting. In effect it is as follows:—Two selenium cells are placed in series in the circuit between two batteries of accumulators, and between the cells and batteries is placed a bridge carrying a galvanometer, such as is used in photo-telegraphy, and arranged in such a way that the receiving cell is illuminated by a source of light which follows the deviations of the galvanometer. One suggestion to effect this is to place a lens between the galvanometer and the receiving cell, and using also a shutter graduated in such a manner that the intensity of the light falling on the receiving cell shall not be proportional to the deviations of the galvanometer, but to a certain function of the same, and which is found by experiment.

This compensator has a second advantage in that the devia-

property of selenium of showing an after effect or inertia when illuminated is overcome by inserting another selenium cell as a compensator in the receiving apparatus. This does not do away with the lag in the transmitter, but as it is of the opposite direction, the two inertias are compensated or balanced.

A further improvement has been made in the galvanometer. The old sluggish needle has been replaced by a more agile swinging galvanometer, and thus the time of transmission shortened and the pictures are sharper.

The great improvement in the results will be at once seen by comparison of the reproductions of Professor Korn herewith with that published on p. 525 of the B.J., July 7, 1906.

Excellent as are the results now obtained by the above method and fruitful as they are of promise, not only as regards the mere fact of the possibility of thus transmitting pictures by wire but also in the possibility of adaptation to illustrated journalism they are surpassed by the announcement that M. Ed. Belin, of Nancy, has transmitted images by wire. We have italicised

the phrase "images by wire," because this differentiates M. Belin's achievement from Professor Korn's. The latter transmits a photographic image and receives it on to a sensitive surface, which is subsequently developed. M. Belin, on the other hand, transmits an image formed in a camera and repro-

M. Edouard Belin, Nancy.

duces the same without the interposition of a sensitive plate or sensitive paper. The inventor wisely withholds full details of all the necessary arrangements have been made, and then promises to give us further information, with illustrations. M. Belin says:—"Actually, as has been announced in the

papers, my final apparatus has been made, and as soon as the adjustments are finished—that is to say, very soon, perhaps in a few days, the first trials will be made in France, on a line four times longer than that hitherto used.

"My first experiments were made with an apparatus called 'Simplex'—that was two years ago. It was the outcome of the conclusive results then obtained that induced me to undertake the construction of the definite apparatus.

"The problem which I set myself is more difficult than that which has been solved by Professor Korn: it was to reproduce direct the image obtained in the camera—to photograph—in fact, by electrical means without plate or photographic paper.

"After having tried for ten years to overcome all the obstacles that I had to surmount, I have now attained my end, and I am on the point of making it public.

"As finished, this apparatus is very simple, and always ready to act, and the image of the actual object which the lens at the point of departure sees, is registered at the receiving end, on any simple sheet of paper, either as a positive or negative, at will, by the simple command of a converter of the current.

"My studies have resulted, in fact, not in a unique apparatus, but on a collection of processes, which recall and comprise almost all the applications of photography, and of which I cite the three principal ones.

1. "The act of reproducing the image of the camera by purely physical means, without any sensitive preparation, and without a dark-room.

2. "That of making photo-etched plates with a very short delay, and under conditions considerably more economical than at present.

3. "That of reproducing at a distance the image seen by the lens, and that by the simple interposition of a telephone or telegraph wire, whatever may be the distance."

Speculation as to the methods adopted can only be wild and useless, but great as has been the advance made by Professor Korn, there is no doubt that M. Belin's is equally as great, if not greater. The two will make us independent to a great extent of time and distance, for by their aid we shall be able to transmit pictures and scenes by the ordinary telegraph wire, though, possibly, at first only by overhead wires, for obviously to effect this through underground or submarine cables will require a somewhat longer time, in consequence of the high capacity of the latter.

## IS TIME DEVELOPMENT DESIRABLE?

(Abstract of Lecture by Mr. H. W. Bennett, F.R.P.S., and discussion at the Croydon Camera Club).

ENTERING into the arena at the Croydon Camera Club, on the 14th of last month, the first words of the champion of the personal development in development were that he came to be crushed, and, metaphorically speaking, wiped out of existence. Indeed, he humorously added, he felt like Daniel in the lions' den. Without resting any doubt on Mr. Bennett's belief in his own dismal forebodings, which a cheerfully provocative countenance rather belied, it must be recorded that he was neither crushed nor eaten. As to the last contingency, there was really not enough to go around, amongst the many present. The lecturer led off with a direct challenge: Either, he said, the advocates of control in development were thorough-going idiots, or the reverse—a delightful inference, logically arising, as to the alternative mental powers of his opponents.

### "Time" Methods.

Time development methods, according to Mr. Bennett, are based on two assumptions—

(a) That all subjects will yield uniform negatives with uniform development.

(b) That no alteration in the composition of the developer will produce any other result than that given by the unmodified developer.

Those responsible for the introduction of time development were certainly not expert practical photographers, and consequently not conversant with the actual practice and methods of those who had to photograph under varying conditions, or acquainted with the very varied subjects and conditions of working that occur in the everyday practice of many photographers, out of which the best possible results must be obtained. The criticisms of methods he advocated were frequently little less than abuse; but such methods rested, or were based on results, and if these results differed from prevalent theories, so much the worse for the latter. It was not fair to condemn, without any knowledge of the many little points of practice not arising in experimental work.

### The Question of Contrast.

Turning to the question of contrasts, these, in some subjects, the lecturer went on to say, were very great. In many cases the differ-

ence of luminosity of the high lights and shadowed details were several hundred to one. Messrs. Hurter and Driffield assured from an inconclusive experiment that a photographer never had to deal with greater contrasts than 30 to 1. They restricted their experiments accordingly. Moreover, their first paper was contradicted in some important respects by their second. Since a photographer cannot give greater contrast in his prints than that represented by the white of the paper and the deepest black, or other colour of the printing process in use, he must necessarily compress the scale very considerably when dealing with subjects of excessive contrast, and extend, or lengthen, the scale, when called upon to photograph subjects of very short range. In addition, as the contrasts in a subject varied very considerably, according to the brilliancy of the light in which it was taken, the worker is again confronted with the problem of varying his results, as opposed to a simple mechanical rendering. In the majority of cases, the photographer has to represent his subjects by the maximum contrast that his printing process will give, irrespective of the actual contrasts in the subject itself. Hence the necessity of modifying development. Actual contrasts in ordinary work might be so great that with normal procedure the high lights might reverse and yet the shadows be lacking in detail, and how often did one fail to secure any clouds present and the landscape in one plate. Judging from the examples published in Mr. Watkins' manual, all the subjects there put forward showed very little contrast, and here the lecturer pointed out that Mr. Watkins' method of obtaining a factor from the first appearance of the high lights might, under certain conditions, lead the worker into grave error.

#### Modifications in Development.

Modifications in development to suit different subjects may be either of two forms, or a combination of both.

(a) Variation in time, or degree of development, the solution itself remaining unchanged.

(b) Variation in the composition of the solution.

Considerable modification in results, the lecturer said, may be secured by either method, though greater control was afforded by the latter rather than by the former. The possible modifications in the composition of the developer were: (a) Increase of bromide, giving weak shadow detail, and greater contrast throughout the print; and (b) increase of the alkali, giving stronger shadow detail and less contrast; (c) dilution of the developer, with or without increase of alkali, resulting in relatively stronger shadow detail, or the maximum strength of shadow detail, with a very soft scale of gradation. In this connection, the lecturer added in parenthesis, Messrs. Hurter and Driffield had laid a curse on alkaline developers, which they had subsequently removed in part. Personally he was a strong advocate of that alkaline developer known as pyro-ammonia; no other was so flexible in his hands. This closed the case for the "modern Daniel," the foregoing comprising the salient points brought forward, avowedly to found a discussion upon. The paper was illustrated by various curves of readings arising from modifications of the developer, but as Dr. Mees pointed out, the points in the curves were not given, and no checking was possible.

#### Discussion.

Mr. E. A. Salt, who opened the discussion, said he would only deal with one or two points which Mr. Bennett had raised, otherwise he might find himself in the novel position of openly agreeing with the chief lion of the den, Dr. Mees. The main point to consider—irrespective of the abstract merits and demerits of the two systems of development—was, which system was best adopted for the beginner, the occasional worker, and the expert. A negative had to be developed for the printing process in view. Personally, when dealing with a large batch of negatives, after the first two or three had been developed, he believed he could gauge matters more exactly than any time, or factorial, system could achieve. It would be different if he had to develop a few isolated negatives at intervals. Mr. Watkins' system was approximately correct, regardless of subject, if a diminished factor were taken from the first appearance of the half-tones. In every-day subjects it was obviously more convenient to note the appearance of the high lights, and probably sufficiently accurate. With time development, over-exposure—in the absence of partial reversal—produced a dense negative, slow to print; a much thinner negative of the same printing value could be

obtained by the initial addition of bromide. He was rather surprised to hear a weak, restrained developer recommended for subjects containing violent contrasts. Surely this would mean securing most of the halation probably present. In such a case he should prefer to apply a powerful non-bromided developer, such as metol or rodinal, as warm as the plate would stand without fogging, so development at an early stage, and intensify if necessary. There was nothing new in this; indeed, he doubted whether much could be said on a subject which brought to mind the now distant battle of the toning baths.

#### The Case "Against."

Dr. C. E. Kenneth Mees, alluding to the lecturer's observation that advocates of "time" and "factorial" development were not practical photographers, pointed out that it was frequently better to regard matters from an outside standpoint. Messrs. Hurter and Driffield's work lost no value because they were, so to speak, "outsiders." It was strongly believed time development would do all that was necessary. It fell to his lot to develop a large number of negatives each day. If only visual inspection was required he developed by inspection and then generally dropped the negatives in the waste-paper basket. On the other hand, if the negatives were wanted to be kept developed by time. He quite agreed with Messrs. Hurter and Driffield that alkaline developers were unreliable, and unsuitable for purely scientific work, owing to the impossibility of following the reaction in alkaline developers, and the great difficulty of reproducing the same developer a second time. With the ferrous-oxalate developer the same result could be obtained over and over again with certainty. It was capable of easy analysis, which was not the case with alkaline developers. With the latter there were unknown double reactions. The chemical action of the former had been thoroughly worked out, and Messrs. Hurter and Driffield were quite right in developing it for scientific work. A practical objection to its use was that it reduced "speed" by about one-half. It was quite true that Messrs. Hurter and Driffield had first placed "a curse" on alkaline developers, and afterwards adopted pyro-soda for "speed" determinations, but they never abandoned ferrous-oxalate for scientific purposes. In reference to the apparent discrepancy alleged by the lecturer in Messrs. Hurter and Driffield's work, fairness it must be remembered that their first paper was based on work done with very inaccurate instruments. Eight years further investigations naturally modified earlier conclusions. He (the speaker) and Dr. Sheppard, when they started their investigations with accurate apparatus, formed a preconceived opinion that Messrs. Hurter and Driffield were wrong in many of their deductions, but were forced by facts to agree with them in almost every particular. Mr. Bennett had laid stress on the fact that Messrs. Hurter and Driffield's measurements only applied to given limited light intensities. He (Dr. Mees) doubted whether this was so. Anyway his confirmatory experiments and conclusions embraced a ratio of contrasts of 1 to 4,000, which he hoped would be considered sufficient. In reference to variations of strength in the developer, increase of additions of alkali, etc., Dr. Mees pointed out that the characteristic shape of an exposure curve was very difficult to modify. Only the top, or over-exposed, portion could it be so modified, and the effect this extraordinary additions to the developer were necessary. With many of the lecturer's curves and arguments he was in accord—they were, indeed, obvious from Messrs. Hurter and Driffield's work. They had, for instance, shown the effect of the addition of bromide, and the increase of alkali in the developer. Mr. Bennett had stated elsewhere, no doubt with truth, that the "gum" work did not control the process, but the process controlled the "gum" worker. Similarly, he believed that when Mr. Bennett thought he was controlling pyro-ammonia, this rapidly altering developer was controlling a very fine architectural photographer. If Mr. Bennett would give him, or anyone else, definite instructions for a definite use of pyro-ammonia, it would be most useful. It would also be a large undertaking. The real crux of "time v. tentative" development was, whether the practical worker could not get better average results by developing for a definite time with a standard developer at a definite temperature (variations of temperature being allowed for), or by Mr. Watkins' system of factorial development, rather than by the old-fashioned method of tinkering with the developer and judging density by visual examination. In all ordinary work he used a Watkins exposure meter, and adopted the first course mentioned.

ned, with perfectly satisfactory results. The range of contrast in an ordinary landscape subject did not, as a rule, exceed 1 to 30, and an ortho plate and screen should easily secure a correct representation of clouds and landscape on the plate. In some interiors there were, of course, an enormous range of contrasts, and special methods applicable to these did not necessarily apply to the general results of photographic work. As to dilution of the developer, dilution gave no advantage, provided that the normal developer contained no bromide. Dilution of a non-bromided developer had no effect on the inertia point. If bromide is present, dilution did make difference.

### Varied Views.

Mr. J. M. Sellors thought that scientists were apt to look upon negative as the result not purely as a means to an end, like an ordinary mortal regarded it. He had given time development a fair trial, and did not consider it a satisfactory system. Whether he was imbued with imagination or not, yet he believed he could control results with the personal factor. Take the case of a subject with extreme contrasts, and there were many; here dilution of the developer, in his opinion, helped considerably towards a harmonious negative. He differed from Dr. Mees that with an ortho plate and adjusted filter, any clouds present could be invariably recorded on the plate—in some cases they were, in others this was not the case. Mr. F. W. Heeks said he had been converted to time development; it gave him what he wanted. The question of large contrasts had been raised. Much of his work consisted of marine subjects, and the dark sails of some fishing boats, against a luminous sky, might be considered in this category; yet in practice, with a fairly full exposure, he had found no difficulty in obtaining good, soft-printing negatives. The Vice-chairman, Mr. F. J. Terry, said he had not adopted time development for choice, but of necessity. He habitually used a panchromatic plate with adjusted filter, and quite agreed with Dr. Mees as to the retention of clouds. If present, he had never failed to secure them. Mr. R. Compton, referring to an observation of Mr. Bennett's, pointed out that although Mr. Watkins stated his system afforded the same relative contrasts, yet he also been careful to add this was not necessarily wanted, and might be varied according to requirements.

### The Reply.

Mr. Bennett, in reply, stated Mr. Watkins had said many things, but invariably strictly in accordance with each other. He cordially agreed with Mr. Sellors that the negative must be made to fit the printing process, and therefore to be considered only as a means to an end. From a "trade" point of view it was imperative not to use a single exposure if it could be helped, and, having this in view,

no time system could be trusted. He did not base the conclusions he had arrived at on conjecture; he had tried time systems, and they had failed him. If he could have got the same results by a simpler procedure than he had been compelled to adopt he would have welcomed it gladly. With accurate exposures upon fairly uniform subjects, no doubt the time system was satisfactory—like conditions, like results. Apart from these conditions, other means must be adopted to secure uniformity. He did not propose imitating Dr. Mees' method of dealing with negatives visually judged by relegating them to the waste-paper basket. In dealing with a flat subject a strong negative must be obtained, or *vice versa*. He pitied a poor, unfortunate operator who gravely told his employer that a flat and unprintable negative was a correct and scientific Hurter and Driffield translation in monochrome of the original scene. The operator might find things "flat" subsequently in another sense. Of course, he believed strongly in correct exposure, not in modifying methods to counteract avoidable errors in a contrary direction. He also agreed with Mr. Sellors' remark that it was not always possible to secure clouds and landscape on an ortho plate with filter in use. He used to employ orthochromatic plates exclusively, but had returned to "ordinary" brands, owing to certain advantages they possessed. Dr. Mees had said that some of his results and conclusions were obvious from Messrs. Hurter and Driffield's work. If this was so, why, then, did "time" advocates object so strongly to the principles he enunciated? Most of them were in direct opposition. (Dr. Mees here pointed out that their earlier papers were very little known. The lecturer dissented.) No doubt time development for beginners was very useful, but the advanced worker should discard such fetters. As to ferrous-oxalate, this might be a useful developer from a scientific point of view, but did not appeal to the ordinary photographer. It was true that with pyro-ammonia one never knew its exact constitution at any given moment, but what of that? It certainly did not oxidise so rapidly as pyro-soda. In some cases he had known development to proceed regularly with the former, without any further additions of the accelerator. In his (Mr. Bennett's) opinion, when Mr. Watkins recommended variable factors, he, in effect, admitted all he was advocating. Dr. Mees had himself admitted that exceptional measures might be taken for exceptional cases. So much being granted, he felt justified in assuming that the same principles, *mutatis mutandis*, applied throughout. He did not agree with Dr. Mees' dictum that a scientific investigator could have a broad grasp of any subject, unless he equally had a grasp of all details necessary for its application in practice. He extremely regretted that the lateness of the hour, and the desirability of his catching the last train home, compelled him to leave some of the points raised unanswered. At the instance of Dr. Mees a cordial vote of thanks to the lecturer was adopted.

## A NEW METHOD OF MEASURING THE TIMES AND EFFICIENCIES OF PHOTOGRAPHIC SHUTTERS.

A Paper read before the Optical Society, and to whose official organ, the "Optician," we are indebted for the illustrations.

THE work on which the following paper depends was undertaken at the National Physical Laboratory, to provide a test for photographic shutters. The resulting apparatus has been used to measure the times of exposure given by several different types of shutters, and these actual times have ranged from one four-hundredth of a second to two seconds.

There seems to be no reason why much shorter times than one-fourth of a second should not be measured by the same means; but the shutters under observation in no case gave a more rapid exposure with the lens of the apparatus. When the time is longer than two seconds, or even one second, one can actually time the shutter with a stop watch, with quite sufficient accuracy.

The optical principles on which the method depend are first briefly explained. An electric lamp with a long straight filament is set up in a vertical position. By means of a lens, an image of the filament is formed. A shutter is put over the aperture of the lens, and if this shutter is set and released, the image of the filament

is formed, and exists for just the time during which the shutter is opened. We thus have to determine the time for which the image exists.

For this purpose a disc is mounted on a shaft, so as to be free to rotate. It is put in such a position that the image of the filament is formed on it. A radial slot is cut in this disc. The light from the point of the image which is formed at the slot passes through the slot, and is visible from behind the disc.

Now let the disc be turned through an angle. If the image is still existing, the portion opposite the new position of the slot is now visible from behind the disc. In fact, as the disc is turned, different portions of the image become visible. Now, suppose that by means of the shutter the image is only formed for a short period, and let the disc be rotated uniformly, assuming for a moment that it is crossed by the image, when the image is formed. Until the image is formed nothing is visible from behind the disc. As soon as the image is formed the portion opposite to the slot at once becomes

visible from behind the disc, and the other portions of the image are exposed in turn until the shutter closes, and the image ceases to exist.

It will be easily seen that the different portions of the image are exposed, if the time for which the image is formed is lengthened or shortened. In fact, while the image exists, it is exposed at a definite rate by the slot in the rotating disc. That is the same thing as saying that a particular length of image is exposed when the image exists for a given time. From a measurement of the length of image we can infer the length of time for which the image exists. In this way we reduce the timing of the shutter to the measuring of the length of a strip of light.

In practice, a disc having a number of slots is used; this being necessary to ensure that the image should be exposed, as above described, whatever the position of the disc at the moment at which the image is formed.

Fig. 1.

The essential features of the apparatus employed in carrying out the optical method just described, are:—

- (1) A lens of large aperture (say two inches) and short focal length (say five or six inches).
- (2) A source of light in the form of a long strip.
- (3) An opaque, circular disc, in which some radial slots are cut, mounted on a shaft, which can be rotated at any speed within certain wide limits.
- (4) A mechanical device for releasing the shutter under test at a definite phase of the position of the disc.

In the apparatus made at the National Physical Laboratory, an electric light—a "linolite"—with a long, straight filament is used as the source of light. An image of this is formed by the lens, which is put in a position so as to give unit, or somewhat greater, magnification. The circular disc is placed in the image plane, and only those portions of the image which cross one or other of the slots in the disc can be seen by an eye placed behind the disc.

There are ten equidistant radial slots in the disc, and the image must be long enough to always extend across at least two of these; that is, it must subtend at the centre of the disc an angle equal to twice the angle between two consecutive slots. When the disc is made to rotate different parts of the image become visible; in fact, if the disc turn with constant angular speed, a definite amount of image becomes visible in a given time. The slots all extend between circles of  $2\frac{1}{2}$ " and  $4\frac{1}{2}$ " radius, respectively.

Fig. 1 shows the position of the image relatively to the ten slots 1–10. When viewed from behind the disc, the amount of image shown, while the disc turns until the slots have the positions indicated

by the dotted lines, is shown in Fig. 2. To see this, it is but to put up a piece of ground glass, close behind the disc, on which the image may be formed. If we can observe the angle subtended at the centre of the disc by the amount of image exposed by any slot, and if we know the mean speed of the disc, we can infer the length of time taken by the disc in turning through this angle.

Now, suppose we rotate the disc at a known speed, and for a short time allow the light from the source to pass through the lens, we can find this time by measuring the angular length of image. Let  $\theta$  be this angle,  $n$  the number of revolutions of the disc in one second,  $t$  the time in seconds for which the image is formed, we have the relation—

$$\frac{\theta}{360} = nt \text{ or } t = \frac{\theta}{360n}$$

Fig. 2.

Now put up the shutter to be tested close in front of the lens. So long as the shutter uncovers any part of the lens, the complete image is formed; the lens having, if necessary, a stop placed in front of it to ensure this being the case. Thus, the time for which the image exists is the complete time of exposure given by the shutter over the lens aperture. This time is the " $t$ " of the formula written above, and so can be determined by measurements of  $\theta$  and  $n$ .

To measure the angle  $\theta$ , the positions of the two ends of the portion of image exposed by one slot of the disc must be observed, and we must avoid certain of the portions of the image. Thus, in Fig. 2 we may measure the portions exposed by slots 1 or 2; but that exposed by slot 10 is, obviously, not complete, as for the first part of the motion of slot 10 no exposure occurs. So it is a safe rule to always measure an inner portion of the image.

The image only exists for a short time—the time  $t$ —and it is, of course, impossible during this time to make observations of both ends. The time for which any part of the image is visible is simply the time for which persistence of impression on the retina continues. This is probably about one twenty-fifth of a second. All that can be ascertained in this time is whether an end of a portion of image lies on the cross-wire or not. So it is clear that more than one observation is required.

If, by hand, we set and release the shutter more than once, the appearance of the image is in each case different. Fig. 3 shows three such different appearances. The positions we wish to measure vary on each setting and release of the shutter, though the whole angle subtended at the centre of the disc by each inner portion

is every time the same, provided the shutter has a constant performance.

The several appearances shown in Fig. 3 differ from each other, because the shutter in each case was released at random, as far as the angular position or phase of the disc was concerned. If the shutter is always released when the disc reaches a definite position, or is in a definite phase, the appearance of the image on the ground glass will, in each case, be the same. It is arranged for mechanically, in a manner to be described, that this shall always be the case. By this means the observer can have as many repetitions of the portion of image he wishes to measure as are necessary. All is now quite straightforward.

Fig. 3.

Fig. 4.

A piece of ground glass with a cross-wire, or line marked on it, is moved up and down in front of the image. It is adjusted after a few releases of the shutter to one end, P, of the image, P. (Fig. 3a), to be observed, and a reading on a suitably graduated scale is taken. The same is then done for the end Q, and the difference of the readings for P and Q gives the angular length of P Q; that is  $\theta$ . The speed of the shaft remains to be measured, and then  $t$  is known. The actual details for the measuring of  $\theta$  are shown in Fig. 7, and described later. The whole process may be gone through very rapidly after a little practice.

When the exposure given by the shutter is anything shorter than one-twenty-fifth of a second, all the portion of the image exposed by one slot on account of its persistence on the retina appears visible at the same time. This fact may be made use of to avoid measuring  $\theta$ , and affords an alternative method of finding the shorter times of a shutter. The speed of the disc is increased until the image is just complete—i.e., the portion exposed by one slot of the disc just joins up to the portion exposed by the adjacent slot. In this way the angle  $\theta$  is known to be the angle between two consecutive slots in the disc. All that remains to be determined is the speed at which the disc is turning. However, there is some difficulty in adjusting the speed to just the right amount; and, of course, a number of releases of the shutter are wanted, with an increase of speed of the disc between each. Further, one has to be very careful not to increase the speed too much.

Fig. 4b shows the correct appearance of the image; but it is clear that the appearance is substantially the same if we speed up the disc further than the desired amount. One can make certain of

not doing this by leaving a slight gap between the successive portions of image; when one is sure that the speed is not quite high enough. Or, it is possible, by continually moving the source of light, to make the image appear, as in Fig. 4a, instead of Fig. 4b. One can then be sure that the correct speed of rotation has been found. The shape of the curves in Fig. 4a depends on the kind of motion given to the source. If this is moved with simple harmonic motion, these curves are portions of sine curves plotted against a tangent scale of abscissas.

At best it is rather difficult to see certainly when the image becomes complete, or nearly so, since the break may come at any position, and the continued straining to see if the breaks are just present or have just disappeared is very tiring to the eyes. For a few observations the method is sometimes useful, for times shorter than one-twenty-fifth of a second.

The appliance, with mechanical release of shutter, has been found much superior in this and other respects. It has been used successfully for finding various times of exposure ranging from two seconds to one-four-hundredth of a second; the times being those given by one or other of several different types of shutters, including a focal plane shutter. It will be seen that the method does not depend on the period of persistence on the retina, and so is applicable to times shorter than one-twenty-fifth of a second.

As far as I have been able to ascertain, all shutters may be released by a small motion of some accessible part. In many cases there is a trigger, while in others a ratchet has to be released. In the mechanical device, above alluded to, for releasing the shutter at a definite phase of the revolving disc, a cam K (see Fig. 5) is mounted on the same shaft which carries the disc, but at the end

Fig. 5.

Fig. 6.

of the shaft remote from the disc. A system of bars, A B C D E B, is freely jointed at the corners B, C, D, E. Near B a bar F G is rigidly fixed to the bar A B C in a direction perpendicular to A B, and this bar F G works against the cam K. The bar B E is fixed to the bed plate of the whole apparatus. One end of a strong spring is attached to the bar A B at A, and this keeps F G in contact with the cam K.

J. DE GRAAF HUNTER.

(To be continued.)

## PATENT-LAW ABUSES.

IN view of prospective legislation on the subject, the paper read before the Society of Arts on "Patent Law Reform" by Mr. J. W. Gordon, of the Middle Temple, was of special interest, and attracted a numerous audience.

The first International Exhibition of 1851 had a marked effect in promoting the reform of the Patent Law. Advantage was then taken of the presence of numbers of Colonists to elaborate a system of Patent Law applicable, not to the United Kingdom only, but to the British Empire as a whole. To put the machinery in thorough working order Parliament passed the Patent Act of 1852, which furnished the high-water mark of English legislation on the subject. It was by no means final, and an opportunity for a grand development upon its lines occurred in 1883, when the next measure of reform was taken in hand; but that opportunity was missed, and the form of statute adopted by most of our self-governing Colonies and larger dependencies then put an end, for a time, at least, to all developments in the direction of drawing the Colonies to the Mother-country. The place of the destroyed system was now being taken, but very inadequately filled, in the International Convention.

The Act of 1902 had crowned and completed the work of 1883. There were two perfectly distinct reasons for which applicants sought patent grants. One applicant desired to practise his invention and create by it a profitable trade; another desired not to practise trade, but to control it. The second asked for an injunction to restrain the manufacture of which he complained. The effect of this was to be found in the well-known case of the Blackley Red Dye, in which the patentee of a brown dye stuff, which proved of no commercial value, successfully restrained the manufacture of a prosperous red dye, because it was conceivable that incidentally and momentarily in the manufacturing operation the red dye stuff passed through a brown phase. The commercial result was disastrous, for a large dependent dyeing industry passed bodily from Lancashire to Holland.

All the schemes which predaceous patentees had elaborated for obtaining control of trade turned upon the injunction, and the growth in recent years of granting injunctions without regard to incidental consequences had dethroned reason in our courts of law. The mischief had now gone so far that a remedy must be sought at the hands of the Legislature.

In the course of a conversation with a representative of "The Tribune" on the subject of his paper, Mr. J. W. Gordon said that any arrangement with the Colonies in the matter of patent-law reform would naturally be reciprocal, but the rights could only be inchoate, for a patent that might be perfectly good in one part of the Empire might touch an industry that was perfectly well known in another. With a proper reservation of these rights there was no reason why the old system worked out in 1852 should not be re-imposed.

The Germans imported from us the coal-tar products from which the aniline dyes were made, and were able to send us back the completed articles because, through the possession of controlling or blocking patents, they commanded the British markets. Injunctions at present governed the operation of the law, but an injunction was a thing that ought to be granted with great particularity. The governing considerations of future legislation should be that there must be no further mischief from injunctions, and that due consideration must be given to the effect of the reproduction of any statute passed in this country upon the legislation of the Colonies.

## LANCASHIRE AND CHESHIRE PHOTOGRAPHIC UNION.

THE first annual meeting of this union was held in the rooms of the Manchester A.P.S. on Saturday, 8th inst., with the president (Dr. C. Thurstan Holland, F.R.P.S.) in the chair.

The hon. secretary reported the rapid expansion of the union into 41 societies, with 74 delegates and a membership of thirty-three hundred associates, from which a staff of 89 lecturers, with 172 lectures or demonstrators, had been enrolled. The financial statement showed a balance to the credit of the union.

The officers elected for 1907 are: President—Dr. C. T. Holland, F.R.P.S. Vice-presidents—Rev. H. W. Dick; T. Lee Syms, F.R.P.S.; C. F. Inston, F.R.P.S.; S. L. Coulthurst; and Dr. A. Hamilton. Hon. secretary (print portfolio section)—Dr. A. T.

Lakin. Hon. secretary (lantern slide section)—T. Hudson. Hon. auditors—J. Hawkins and J. Smith. Hon. business secretary and treasurer—W. Tansley, 22, Chapel Place, Liverpool.

The jury of selection for union prints and lantern slides are Dr. C. T. Holland, F.R.P.S.; Rev. H. W. Dick; S. L. Coulthurst; C. F. Inston, F.R.P.S.; J. J. Rothwell; T. Lee Syms, F.R.P.S. and F. Whitaker.

The following were selected for judging societies' competitions and exhibitions—viz.: F. Anyon; A. A. Bellingham; Tulloch Cheyne; A. W. Cooper; S. L. Coulthurst; Dr. T. G. Crump, B.A.; Rev. H. W. Dick; Dr. J. W. Ellis, F.E.S.; T. Glazebrook; Dr. C. T. Holland, F.R.S.; C. F. Inston, F.R.P.S.; Dr. A. T. Lakin; J. Shaw; T. Lee Syms, F.R.P.S.; and J. W. Wade.

## Exhibitions.

## SOUTHAMPTON CAMERA CLUB.

THIS week the Southampton Camera Club is holding its sixth annual exhibition, and the collection of pictures gathered together in the Philharmonic Hall is sufficient evidence, if such were needed, of the steady progress of photographic art from year to year. This is apparent both in the open classes and in those confined to members of the club, and the judges expressed great satisfaction with the exhibition as a whole, the members' pictures showing a considerable improvement.

Southampton is this year the last of the three great Southern exhibitions held in conjunction with one another, the others being Southsea and Hove. Year by year these exhibitions obtain greater favour with the exhibiting workers, owing, in great measure, to the good management which directs them, and the general desire on the part of the local committees to keep ahead of the times. Indeed, it is not too much to say that exhibitors now look forward to these three exhibitions as a prominent feature in their calendar, and no provincial exhibition receives better support from them than is accorded to the Southern three.

Not only is the pictorial quality of the exhibits higher than in past years, but there are about 100 more frames on show than was the case a year ago. The number of pictures in the competitive section reaches 650, but the increase has not caused crowding of the frames, and every picture appears to have been hung to advantage.

Turning to the pictures, the first screen holds the work of the local members, and here the powers of the judges must have been severely taxed to decide which pictures should receive the awards at their disposal. Taking the names of the exhibitors in alphabetical order, we find that A. D. Bacchans shows three interesting technical studies, the best being "Jersey Green Lizard." T. L. Baker has a dainty yacht study in "Summer Calm," the reflections of the sail in the limpid water being very pleasing. Mrs. Baker shows two excellent flower studies, "Roses" being the better rendering. R. C. Batt has three frames, of which "Z'mutt" is generally preferred. Dr. A. E. Bodington shows "A Rainy Day—Florence" and "Hesitation," the latter a charming study of cats. O. P. Butler's one picture, "A Thames Backwater," has been considered good enough for an award, and the general opinion concurs with that of the judges, the atmosphere nicely relieving the somewhat formal composition. General Byam, C.B., gives a good interpretation of motion in his "Yacht Racing on the Solent," though the light mount is not in perfect harmony with the print. C. M. Cooper's natural history subjects are almost pictorial, whilst losing nothing in technical excellence. His best frame is entitled "Bird Studies," a series of eight prints representing different birds amidst natural surroundings. "The Cuckoo," by the same worker, calls for more than ordinary attention, the attitude of the bird being extremely lifelike. Cecil Daw is represented by six pictures of which "The Artist" is easily the most noteworthy. If the high light is somewhat strong, it is the only fault that can be found with this picture. The worker has caught a most natural expression and the lines of the composition are well arranged. "Homeward" is somewhat spoilt by the heavy sky, and the rendering of the tones is not altogether convincing, and "A Bit of Old Whitby" is somewhat too crowded and low in tone. H. Daw's "Alongside the Quay" is his best work, the composition and atmospheric effect being distinctly

good. H. Essex is a prominent prize-winner this year, and has scored deservedly with "A Woodland Prelude." This title is well borne out, the morning sun casting soft beams of light through the grey mist which hangs upon the wood. Other noticeable pictures by Mr. Essex are "Early Morning in a St. Malo Street," a study of "Cherries," and a well thought-out portrait entitled "Do you take Sugar?" the only defect in the last-named picture being the somewhat scattered lights. It is, however, in the lantern slides that Mr. Essex has achieved his greatest success, having received no fewer than four awards, although the rules will not permit him to take more than two—the Club Salver and "The Photographic News" Medal. "Lighting Up" is a good portrait by Geo. Fuidge. The model is portrayed lighting his pipe, but a little doubt exists as to the source of light, which for a picture of this class does not seem sufficiently concentrated. A. Gibbings has a good rendering of sunlight and shadow in "In Cloistered Shade," and also shows a Continental street scene entitled "In Old Savoy." A. E. Henley is one of the club's oldest workers, and this year he has again shown improvement upon his past work. His renderings of fruit and flower subjects are becoming quite well known. "Bon Chrétien Pears" is a splendid piece of technical work, though the judges have preferred "Yellow Plums," which has received an hon. mention.

In the open classes, Mr. Henley exhibits "White Hearts," which possesses greater pictorial excellence than those works already mentioned, but the rendering of the cherries is not quite what we look for from this worker. "A November Sunset" has been awarded one of the coveted salvers, and in this picture Mr. Henley has produced a delicate and pleasing rendering of sunlight reflected in the wet sand. E. J. Jarvis has received a medal for "Silent Witnesses of Former Splendour." Mr. Jarvis is a new exhibitor, but the award he has received this year should encourage him to attempt more ambitious work in the future. A. J. Kay is represented by two sets of lantern slides, which show artistic ability in a pronounced degree, but which lose somewhat by their coldness of tone, and he would do well to adopt the more modern "browns" in landscape slides. C. D. Kay has been awarded the "Amateur Photographer" Medal for "Sunlight," which has thus been nominated the best picture in the members' classes. It represents an old house upon which the shadow of a quaint tree has been thrown by the evening sun; the tones are pleasing, the composition leaves nothing to be desired, and the picture is a general favourite with the public as with the judges. Other pictures by the same exhibitor are "The Rev. Dr. Kay," a powerful portrait, and "Mr. S. G. Kimber," an excellent representation of the popular Southampton secretary. "A Portrait of My Mother" is unconventional, and if for that alone attracts considerable attention. Another member, W. R. Kay, exhibits no fewer than seventeen pictures; indeed we think it would be better if this worker were to confine himself to fewer frames and endeavour to have more equality in his results. He takes an award for "Lux in Tenebris," a good rendering of sunlight in a cathedral crypt, and an honourable mention for "Drifting." We also notice a series of portraits by Mr. Kay of prominent members of the Southampton Camera Club, of which that of the President, Mr. Burrough Hill, is perhaps the best. In the open classes Mr. Kay has four frames, including "The Tree that Grew by Itself," a picture which last year roused much criticism. Miss Bowden-Smith's best picture is "The Afterglow," though we think that a more suitable mount might have been chosen. G. F. E. Kenny has only one picture, "Cloisters—Muckross Abbey," which shows good quality, the rendering of sunlight on the old pillars being exceedingly pleasing. S. G. Kimber's name is well-known as an exhibitor, and once more he scores heavily with his architectural pictures. "A Rainy Day, York," shows, however, that architecture is not the only subject with which Mr. Kimber can deal successfully. The picture takes a well-deserved award, and, indeed, it is difficult to imagine how the judges could have overlooked it. Two of Mr. Kimber's cathedral pictures have received hon. mention, the best being "In the North Transept—York Cathedral," though "In Peterborough Cathedral" runs it very close. Mr. Kimber's further versatility is evidenced by the fact that "Innocence," a charming nude study, has also received a mention. The rendering of the flesh is particularly good, although the shadows are somewhat heavy. The same exhibitor also receives a mention on a slide, entitled "A Norman Crypt." "Pines," by H. H. Longman, has a weird effect. George Mason shows a technical architec-

tural picture in "The Cloisters—Fountains Abbey." "Roses" is a decorative arrangement by H. W. Miles, who also exhibits a tastefully mounted woodland scene entitled "Guardians of the Glade." Dr. H. Milner-White exhibits, not for competition, a series of interesting Egyptian studies. Some of these represent architectural remains, the sculpture being clearly defined, and the others representing native customs. R. E. Parson shows three pictures of varying interest, "Speed," perhaps, being the best. "A Tidal Harbour" is well rendered, but rather crowded. E. E. Rye exhibits some creditable landscapes, of which we prefer "Early Morn on the Common." R. Robinson has a capital architectural study in "A Sunlit Doorway," and his "Portsmouth Harbour" has a fine suggestion of sunset about it, but the shadows are too heavy. F. G. Ryder has been a prominent member of the Southampton Camera Club for some time, but this is the first time that he has come to the fore as an exhibitor. "An October Sunrise" is a fine rendering of sunlight and mist, and would have won in a stronger class than that in which it was exhibited. A similar picture entitled "The Hill through the Wood," is not far behind its companion. T. E. Smith's best picture, "Where Storms Blow Fiercest," is an uncommon specimen of English landscape, its most attractive feature being the luminous sky. Amongst T. M. Weaver's exhibits "Saxon Font, Wells Cathedral," is the most attractive, and must have fallen but little short of the judges' standard; indeed, it is probable that only the small number of awards at their disposal prevented his securing success. "Gooseberries" is a splendid piece of work, of not too severely technical a nature; and an original study, "The Cloister Door, Wells Cathedral," by the same worker, has distinctive merit. Mrs. Weaver secures a mention for her "Flower Study," which work is far in advance of her "A Summer Evening." Smith Whiting is a new exhibitor, but his work proves him no novice in natural history subjects. "Avocet on Nest" secures for him one of the club's salvers, and others of his pictures scarcely fall below this in merit. The rendering of plumage in "Starling" is exceptionally good, and "Hawfinch" and "Robin" are quite pictorial, whilst losing nothing in technical excellence.

Turning to the open classes, it is readily observed that few prominent exhibitors are unrepresented. Mrs. Arbutnot has three pictures, of which "Assissi," perhaps, reaches the highest standard of excellence. James C. Batkin exhibits "A Rift in the Fog," a picture which meets with nothing but praise on all hands. His other two frames will also repay studied inspection. Robert Burney has acquired a great reputation for fruit and flower studies, and this year his work is in no way behind what we have been accustomed to see. B. H. Bedell has two good things, "In Harbour" being perhaps the better. G. L. A. Blair's "Whilst London Sleeps" is well-known, but attracts attention by its bold conception and good execution. Dr. E. G. Boon exhibits four altogether charming pictures, the most attractive being "The Injured Butterfly."

Graystone Bird is a regular exhibitor at Southampton, and this year receives a special mention for his set of slides "Clouds on Snowdon." He also shows several frames, of which "Snowdon Veiled in Grey Mist" is the general favourite. G. A. Booth's set of slides, "Insects," has been considered favourably, and a salver in the technical section, and E. R. Bull obtains a mention in the same class for a set of "Architectural Details." Rev. H. R. Campion exhibits four frames of his highly pictorial architectural work, "Tombs of his Ancestors" being the best. This print is somewhat strong, but a nice sentiment has been weaved into the picture. J. W. Charlesworth shows two excellent sets of lantern slides. R. J. Church has five frames, "Evening in the Solent" being a delightful sunset picture, and James Clark is responsible for "A Study After Asti," a nude figure study in which the flesh tones are delightfully rendered. Wm. A. Clark is prominent this year with four frames and a set of lantern slides, all of which are of high pictorial merit. "Early Morning Sun, Gloucestershire," strikes a high note of excellence, although the modern gas-lamp in the old archway is somewhat unfortunate. W. T. Clegg's "Beam of Light" is a fine cathedral interior, though the source of the beam might be a little more evident. H. Colebrook is a new exhibitor at Southampton, but glancing at his work we hope that he has come to stay. "Old Shoreham" earns him an hon. mention and is unquestionably his best production, but the "Water Meadows" is well

composed and falls but little short of the picture noticed by the judges. H. J. Comley, whose name is well known among colour workers, exhibits two portraits and an excellent still-life study in three-colour work. Dan Dunlop is awarded a salver for "Pensive," a dainty figure study, and Mrs. R. Dunlop's "Child of the Ghetto." Herr Rudolf Dührkoop thoroughly deserves the salver he has been awarded for "The Violinist—Eberhardt," although any of his eight prints might have received the judges' notice.

In the Technical Section, Mr. Frewin takes an award for three large frames forming a series of "Stone Curlews," which is a very interesting set, showing these birds in every stage of development. Dr. Grindrod's portraits are exceedingly good, and C. J. Hankinson shows several pictorial studies. Aubrey Harris has been given a salver for "The Edge of the Wood," a strong, well-composed landscape, and W. A. J. Hensler, E. O. Hoppé, and E. T. Holding, all exhibit notable work in entirely different styles.

Dr. Hutchinson's colour slides are extremely well produced, and well deserve the mention the Judges have accorded them; the colouring of his "Butterflies" being remarkably true to life. Miss Brenda Johnson's work has been well received this year, and it only remains for us to notice favourably "Springtime," the landscape and nude figure forming a picture that is charming on account of its restraint and delightfully "open-air" feeling.

Colonel Johnstone, C.B., exhibits several pictures, of which we prefer "Buoys and Gulls." Fred Judge's "October" and "After the Storm," attract general notice, and the same worker receives a mention for his slide, "Departing Day." Colin Keay shows a picture of highly historical interest entitled "The last Salute," in which a cruiser is paying her last sad tribute as the body of the Great Queen is being borne to Portsmouth from her island home at Osborne.

Ellis Kelsey's slides are fine breezy renderings, and the "Rescue" thoroughly deserves the salver which it has been awarded. Harry Lindoe's "Old Durham" is the better of his two pictures, and we cannot help noticing, in passing, the fine straightforward portraiture of Fraulein Mandl and W. H. Mendelssohn.

Arthur Marshall is a great favourite at Southampton, and year by year almost the first thing one hears on opening day, is "What is Mr. Marshall showing this year?" The "Venetian Pearl" is quite one of the best pictures in the "show," and, generally speaking, we prefer it to "Precious Stones," which takes a salver. Both, however, are magnificent pictures. "The Appian Way," again, is a favourite with some, and, indeed, it is not too much to say that everyone of his eleven pictures has a strong following of admirers, who warmly contend that their favourite is the best. Mr. Marshall takes the special award as the strongest exhibitor at the three shows, Hove, Southsea, and Southampton, and in the decision the general public are at one with the Judges.

Other prominent exhibitors are the Misses Aitchison, A. J. Fuller, J. Dudley Johnston, Adolph Langflier, S. B. Lupton, Ward Muir, O. G. Pike, S. A. Pitcher, Dr. Rodman, H. Y. Simmons, L. J. Steele, and A. G. Thistleton, whilst T. Lee Syms exhibits two of his beautiful figure studies, gems indeed, wherein sunlight and light drapery, two exceedingly difficult elements to successfully combine in one picture, are controlled by a master hand.

J. M. Whitehead is quite in the front rank, and this year his work again shows a decided advance upon what has gone before. The mention he receives for "From the Cloudland," is only what he deserves, for that picture is a masterpiece of impressionistic and romantic landscape work.

The judges were Messrs. Reginald Craigie and H. Snowdon Ward, F.R.P.S., in the pictorial section, the technical work being judged by Mr. Martin Duncan, F.R.P.S., and we can only add that these gentlemen appear to have given general satisfaction, which in an exhibition of this standard must have been a difficult task. A loan collection, including, among other features, a splendid series of 77 portraits and figure studies, by Herr Rudolf Dührkoop, kindly lent by the Editor of the BRITISH JOURNAL OF PHOTOGRAPHY, completes a highly pictorial and interesting exhibition.

There are several trade stalls, and demonstrations of "Dry Mounting" have been arranged for by Mr. Martin, who also shows a good stock of "British Journal Almanacs," and other photographic literature.

## THE NORTH LONDON PHOTOGRAPHIC SOCIETY.

THE following are the awards at the first annual exhibition, given by the judges, Messrs. Reginald Craigie, Furley Lewis, and A. H. Blake, M.A. :—

### OPEN CLASSES

Class A.—Bronze plaque: No. 1, H. Youel Simmons; bronze plaque: No. 2, J. E. Latham; hon. mention, No. 18, Walter Selfe; hon. mention: No. 43, Ellis Kelsey; hon. mention: No. 56, G. H. Pearce. Class B.—Bronze plaque: No. 93, E. O. Hoppé; hon. mention: No. 94, E. O. Hoppé; hon. mention: No. 68, Miss Hild Stevenson. Class C.—Silver plaque: No. 127, C. Willé (best picture in the Open Classes); hon. mention: No. 114, W. A. Clark; hon. mention: No. 120, J. W. Johnson. Class D.—Bronze plaque: No. 142, J. H. Jackson. Class K.—Bronze plaque: W. J. Shelly; bronze medal: Frank Odams.

### MEMBERS' CLASSES.

Class E.—Bronze plaque: No. 209, C. H. Conolly; bronze plaque: No. 167, Gideon Clarke; hon. mention: No. 210, G. Hale; hon. mention: No. 169, Gideon Clarke; hon. mention: No. 212a, Charles Roberts. Class F.—Bronze plaque: No. 225, E. O. Hoppé; bronze plaque: No. 240, G. Hale; hon. mention: No. 238, P. W. Simons. Class G.—Bronze plaque: No. 247, C. Willé; hon. mention: No. 248, E. O. Hoppé. Class H.—Bronze plaque: No. 270, C. Willé; hon. mention: No. 262, W. E. Houghton. Class I.—Bronze plaque: No. 303, R. H. Lawton; hon. mention: No. 296, James Caw. Class J.—"Amateur Photographer" silver plaque No. 351, G. Hale; bronze medal: No. 333a, Charles Roberts; bronze medal: No. 330, R. H. Lawton.

The silver goblet presented by Mr. E. O. Hoppé for the best picture in the Members' Classes is awarded to C. H. Conolly.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between November 26 and December 1 :—

VIEW FINDERS.—No. 26,855. Improvements in and relating to view finders for photographic cameras. Emma Nye, 27, Chancery Lane, London.

SHUTTERS.—No. 26,905. Improvements in or relating to focal plane shutters and other roller-blind shutters for photographic purposes. Arthur Lewis Adams, 26, Charing Cross Road, London.

LENS.—No. 27,370. Orthoscopic and anastigmatic photographic lens. George Lindsay Johnson, 55, Queen Anne Street, Cavendish Square, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

INVISIBLE PICTURES.—No. 23,109, 1905. It is possible to bleach photographic pictures, more particularly those obtained on silver bromide papers, by means of a reducing process in such manner that the picture of chloride of silver becomes invisible upon the paper, but reappears as soon as the apparently vacant paper is exposed to the light.

The picture is caused to fade by the action of chlorides, and some of these are particularly suitable. Chloride of mercury very speedily bleaches such silver bromide pictures, but the invisible picture must be developed, as it will not appear merely upon exposure to light. A number of other chlorides, such as ammonium chloride, magnesium chloride, and sodium chloride do not attack the black silver picture, but furnish an appropriate bleaching medium when copper salts are mixed with them. Even traces thereof render active a solution of sodium chloride, for example, which of itself would be completely inactive.

Pictures of this kind which lie invisibly upon the paper and

which are rendered visible by exposure only, may also be obtained by printing, and this by printing with a colour or ink which in the unexposed condition does not stand out from the support, but becomes visible only when it has been exposed to the light for some time. A colour of this kind may be produced, *inter alia*, merely by grinding chloride of silver with varnish.

Broadly, the following means are employed in the production of such pictures:—

Invisible pictures are formed by photographic means, from negatives which themselves exhibit an incomplete picture, the missing parts being provided by a mechanical printing process. A complete photographic picture is produced, bleached or faded and re-exposed under a negative or stencil which covers certain parts of the invisible picture and only permits a partial picture to remain. A partial picture is produced by mechanical means—for example, by printing from an appropriate block in invisible ink, the missing parts being then printed in from a second block in visible ink. The entire picture is printed—for example, by heliographic or light printing, in invisible ink, exposure being effected as above under a stencil or a negative.

The claims are: 1. A process for the manufacture of pictures and letterpress or inscriptions which become visible only upon exposure to light, characterised by the fact that photographic silver prints are bleached or faded or converted into an invisible silver chloride picture in a bath which in addition to containing various chlorides such as ammonium chloride, sodium chloride, magnesium chloride, and other inactive salts, also contains more or less copper salts. 2. A process for the manufacture of pictures and inscriptions becoming visible only upon exposure to light, characterised by the fact that by means of an ink sensitive to light—for example, chloride of silver ground with varnish—an impression is formed which only stands out upon the paper after exposure. 3. Changing pictures, in which the conversion of the picture is produced by the action of light, characterised by the combination of pictures appearing in the light and obtained by printing by means of ink sensitive to light or by bleaching silver pictures by chlorination, with visible pictures of any desired kind. 4. Process for the production of pictures in accordance with Claim 3, characterised by the fact that various parts of the picture which are wanting in the bleached or invisibly printed picture are supplied by a mechanical printing process in visible ink. 5. Process for the production of pictures in accordance with Claim 3, characterised by the fact that a bleached photographic picture, or a picture printed with invisible ink only becoming visible after exposure, is exposed beneath a negative or a stencil which covers certain parts. 6. A process for the production of pictures in accordance with Claim 5, characterised by the fact that negatives printed upon transparent paper are employed which at the same time remain upon the picture to serve as a protection from accidental exposure until it is desired to produce alteration in the picture. Haseltine, Lake and Co., for Josef Rieder, 16, Ungerstrasse, Munich, Germany.

COUNTING MECHANISM.—No. 25,839, 1905. This invention relates to a new or improved meter or counter applicable especially to photographic cameras, and is for the purpose of indicating the number of exposures made on plates or films so as to avoid the chance of a second exposure upon the same plate or film.

The claims are for: 1. An automatic counting apparatus for counting the openings of photographic shutters and attachable to photographic cameras in such a manner that whatever means is employed to wind or "set" the photographic shutter will displace the lever-arm of my apparatus to the limit of its stroke, and on the release of the camera shutter the said lever-arm is released and returns to its "home" position, causing a fresh number to be shown on the dial. The apparatus with ratchet wheel and lever with the spring attached thereto and working in the teeth of the said ratchet wheel with the detent spring or pawl and the power spring attached to the said lever and case, the dial and the spindle with its milled head or knob and the arrangement of the parts whereby a "setting" action is obtained when the lever is away from its "home" position, substantially described. 2. The stop caused by the thickening of

the base of the detent spring or pawl and the arrangement of the parts constituting a lock when the lever-arm is in its "home" position substantially as described. James Hillman, Rodwell Lodge, Basils Road, Stevenage, Hertford.

METALLOID PRINTING SURFACES.—No. 23,815, 1905. This invention is for the preparation of metalloid surfaces for photographic and mechanical printing by means of solution of gelatine and syrup or honey or fish-glue, in the following manner, viz.:—

1 part of gelatine,  
17-20 parts of water, and  
½-1 part of syrup or honey or fish-glue.

This solution is brought to a boiling point and filtered whilst hot, and in that condition is applied by dipping or flowing over to any suitable surface, as paper (in particular all Baryta papers), wood, ivory, metal plate, glass. The coating is allowed to cool, and then to dry by moderate heat, retaining a sufficient amount of stickiness to apply metal powders and bronzes by means of mechanical contrivance such as bronzing machines, thereby causing the said powders to adhere to the surface evenly and smoothly.

A second coating of gelatine is then applied, which is made up in the following proportions, namely:—

1 part of gelatine,  
20 parts of water

to which add a small quantity of chrom alum to harden the gelatine. This coating is applied to the metalloid surface by allowing it to flow over or by dipping it whilst still hot, and it is then allowed to dry. In the case of copper or brass bronzes or powders it is necessary to apply a coating of celluloid varnish to prevent the acid of the air from acting on the copper or brass basis, after which a further coat of the second gelatine coating is necessary. The material so prepared is now ready to receive carbon prints or printing-out (P.O.P.) or bromide emulsion for ordinary printing or enlarging upon by daylight or artificial light, and is treated in the usual manner as if printing on ordinary or plain papers. Charles Harald Thomson, 1, Brindley Street, New Cross, London, S.E.

COLOURING PHOTOGRAPHS.—No. 5,109, 1906. In place of the usual opaque sensitised paper, transparent sensitised paper, or transparent sensitised celluloid, is used, on which is printed the photograph by the ordinary method. The back or under side of the photograph is then painted in any desired way with oil colours, or with any other suitable medium. After colouring the photograph on the under side, the painted photograph is mounted—paint side downwards—on a white or coloured background, which background may be composed of paper or any other adaptable material.

The claims are: 1. The method of producing coloured photographs characterised by printing the image upon sensitised celluloid, then colouring and backing the same. 2. In coloured photographs the use of a single sheet of celluloid which serves both for the direct printing of the image and the colouring thereof. Albert Beaumont, 23, Bridge Street, Hawick, N.B.

FOCUSSED VIEW FINDER.—No. 5,354, 1905. This invention relates to photographic hand cameras, wherein the focussing of the camera is effected by the aid of a lens other than that for admitting light to the sensitised surface on which the photograph is taken. Various arrangements have been proposed for combining with a camera lens a focussing lens in such manner that both lenses are and remain structurally connected together and travel the same distance while being focussed.

The invention has for its object to avoid such and other disadvantages incidental to such constructions of twin lens cameras, and to enable the camera to be focussed by means relatively small in size and carried by a structure separate from that carrying the camera lens, and adapted to enable the entire view to be focussed, and which will enable the camera lens to be closed up while such means will remain in focus for infinity, enabling photographs for that focus to be taken on the simple outdrawing of the camera without any focussing, and will enable film cameras to be focussed as accurately as plate cameras having an ordinary ground glass screen.

To this end, the invention is characterised by the combination with an adjustable focus camera, of an adjustable focus

view-finder having a lens of focal length some convenient fraction of that of the lens of the camera, in such manner that the view-finder lens and the camera lens will be carried by different structures, and will be disconnected when the camera lens is closed within its focal length, and will be in focus when the camera is set for "infinity," and will, thereafter, be conjointly operated, in the ratio of their focal lengths, by means of a focussing spindle carrying pinions which gear with racks attached to the view-finder and camera structures, and have teeth the ratio of the number of which is equal to the ratio of the focal lengths of the two lenses, so that the general focussing of the camera will be effected by focussing the view-finder.

The claim is: In combination, an adjustable-focus camera, and adjustable-focus view-finder having a lens of a focal length some convenient fraction of that of the lens of the camera, the camera and view-finder lenses being independently mounted and carried by separate structures and adapted to be set in initial focus for "infinity," and racks and differential pinions and a spindle common thereto adapted to conjointly adjust the camera and the view-finder lenses for other foci in the ratio of the focal lengths of their respective lenses, as set forth. Clarence Claxton Blagdon Turner, of 28, Bath Road, Bedford Park, Chiswick, and Stanley Wyndham Jamieson, of 13, Wynn-stay Gardens, Kensington.

## New Apparatus, &c.

A New Distance-finder or Telemeter. Sold by A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, E.C.

This convenient little device takes the form of a bronzed tube of about 5½ in. in length, with an eye-piece at one end, by means of which the grain of a ground glass is sharply focussed; then by a draw tube at the other end the object of which the distance is

required is sharply focussed on the ground glass, and the distance is then read off on the tube. We have tested this upon measured distances, and find it quite accurate, and the range extends from about 7½ ft. to infinity.

It is handy in shape by no means weighty, and will be found of considerable benefit by hand-camera workers. Its price in metal mounting is 10s. 6d., or, mounted in leather and helical draw tube, 21s.

**MERCURY VAPOUR LAMPS.**—Messrs. O. Sichel and Co. write us:—We should be glad if you would call the attention of your readers to the fact that these printing apparatus, and a portrait apparatus made from the same class of tubes, have been very successful, and we have supplied a number of well-known photographers who are using them with every success. A special feature of these mercury vapour outfits is that after the initial outlay (which is very moderate) the cost of the upkeep is very trifling, especially taking into consideration the fact that the electric company will supply the necessary current for these lamps at the power rate, which is calculated on a much lower basis than the lighting rate. During these dull days the photographers to whom we have supplied this light have found themselves entirely independent of the weather, and have been able to finish off orders which under ordinary circumstances would have been impossible, and have consequently improved their reputation. These mercury vapour apparatus are only suitable for continuous current, but in cases where only an alternating current can be obtained we have a new form of enclosed arc lamp with a similar arrangement which has also proved very successful. Any of these printing outfits can be seen at our showrooms, third floor, 52, Regent Street, W. We might also mention that we are supplying to some houses these mercury vapour tubes 45 in. long, capable of taking twenty-four half-plate printing frames, and the cost of an entire outfit with one of these tubes is only £10 10s. As we are very heavily pressed in this department we would be allowed to say that it is necessary for us to have some few days' notice for delivery.

## New Books.

"Photographischer Abseiss-Kalender, 1907." Published by Wilhelm Knapp. Halle a/S. Price 2s.

This is a calendar for next year in which on every page, which bears three days' dates and the times of the sun rising and sun setting, there is a half-tone reproduction of a landscape, and also some useful working formula. It is a fairly bold size (11 x 7), and the printing is excellent. The only point is that there is no index to the formulæ, so that one may have to search through the whole year to find exactly what one wants.

"Hazell's Annual" for 1907 has just been issued this week by Messrs. Hazell, Watson, and Viney, the proprietors of our contemporary, the "Amateur Photographer," and a compendious volume it is of 620 pages. "Current information codified" may be taken as a fair description of "Hazell's," and it is difficult to imagine any better reference volume to men and topics of the time than this volume, which has indeed proved its merits by regular appearance and appreciation for twenty-two years. We have turned to previous issues on many occasions when we desired to verify a piece of information, and therefore our encomiums of the present issue are not solely the result of examining the volume before us. Yet it is, we find, particularly well posted on points into which we looked, knowing what we might expect in such a volume. To cite only one example, under "Copyright" we find an abstract of the case of *Stackemann v. Paton*, the peculiar nature of which we were at pains to point out in our columns at the time. The price of "Hazell's" is 3s. 6d. net in cloth covers.

## New Materials.

The Holborn "Q.D." Postcards. Sold by Houghtons, Limited, High Holborn, W.C.

The special feature of these new gaslight postcards, which we were able to review favourably on their first introduction by the Falla-Grey Company, is that the necessary operations of development, washing, and fixing are quickly done, as they only require ten seconds' exposure at six inches from an incandescent gas burner, fifteen seconds' development in a five-grain amidol developer, rinsing one minute in a 20 per cent. hypo solution, and then washing for five minutes. The results obtained by this method are certainly extremely satisfactory, the whites being clean and the scale of gradation an unusually long one for this class of emulsion, with good blacks. For rapidly turning out in quantities they should be of considerable benefit.

The "Gem" Chloride Plates. Manufactured by the Gem Dry Plate Company, Limited, Willesden, N.W.

The new gaslight lantern plates have in our hands given satisfactory results, though inclining to brilliancy. The whites keep perfectly clean, and the blacks obtainable are very satisfactory. The special developer recommended is hydroquinone with caustic soda, and with this, as with a normal metol-hydroquinone excellent results are obtainable.

Christmas Cards. Manufactured by Chas. Tyler and England Bros., 79, Copenhagen Street, King's Cross, N.

The assortment of samples sent us of the above are quite sufficient to testify as to the good taste and excellence of workmanship, as they are distinguished by pleasing combination of colours and dainty effects, that are likely to be very popular. The styles and prices vary so much that all tastes and pockets are catered for.

A CORRECTION.—In the notice last week of the new Agia fixing salt, a superfluous "not" occurred in the early part of the paragraph. We regret the mistake, though we hope that the context was nevertheless clear. The contradiction involved by the clerical error should have been obvious to our readers.

For the Christmas trade Mr. H. W. Green, of Rotherham, has issued a series of calendar mounts in both paste-down and slip-in patterns. The mounts are known as the "Royal," and take post-card or cabinet photographs. The price is 3s. per dozen.

# Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

Dec.	Name of Society.	Subject.
11	Cardiff Photo. Society .....	"Exmoor." F. Murphy
11	Aberdeen Photo Society .....	"What Can be Done with a Hand Camera." C. P. Goetz
11	Loughton Photo Society .....	"Outdoor Figure Photography." E. H. K. Hillsworth
11	Tunbridge Wells Amat. Ph. A. ....	"Shake-pare at Home." H. Snowden Ward
11	Sutton Photographic Club .....	"A Popular Chat on Lenses." E. A. Salt
11	Aberdeen Photo. Art Club .....	"Slides by Carbon Process." W. Findlay
11	Southampton Camera Club .....	The Exhibition Slides and Presentation of Exhibition and Club Award.
11	Worthing Camera Club .....	"The Simplicity of the Kodak System." P. Phethean
11	Gravesend and Dis. Ph. Soc. ....	Photography as Applied to Decorative Work." E. D. Ingall
11	Lancaster Photo. Society .....	"Recent Advancement in Photography." Wellington & Ward
11	Preston Camera Club .....	Amateur Photographer (1906) Prize Slides
11	Bowes Park Photo. Society .....	"Development of Negatives." "Ozobrome" Dr. Lynam
11	Oxford Camera Club .....	Affiliation Slides.
11	Derby Photo. Society .....	"The photographic Lens."
11	Swansea Camera Club .....	"Sports and Pastime with the Goerz-Anschutz Folding Camera."

11	Greenock Camera Club .....	"Sports and Pastimes with the Goerz-Anschutz Folding Camera."

## ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, December 11, Mr. J.-C. S. Mummery, vice-president, in the chair. A lecture was given by Dr. W. J. S. Lockyer on "Thunderstorms and a Camera," in the course of which the lecturer exhibited many lantern slides showing various types of lightning flash, and gave accounts of the best means of obtaining photographic record of flashes.

CROYDON CAMERA CLUB.—The members on the 5th inst. paid a visit to Messrs. Wratten and Wainwright's dry-plate works. Mr. S. H. Wratten and Dr. Mees, in welcoming the members, respectively gave an outline of the manufacture of dry-plates, and the object and aims of the attached laboratory, the gist of which we publish next week.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—Mr. E. O. Hoppé was announced to lecture at the last meeting of the Society, on "Motive and Sentiment," but was unfortunately too ill to attend; his friend Mr. C. Willé, however, very kindly read his lecture for him. There was a large attendance; among a number of well-known photographers present we noticed Mr. Furley Lewis. The lecturer pointed out that it was only a few photographers who endeavoured to catch the motive of the picture they saw before them. There should be only one motive in each picture, otherwise the interest was divided and the motive lost. It was necessary that the photographer should be able to see whether the charm of a view was in its arrangement or only in its colouring, otherwise he would not be able to get the result he desired. Many lantern slides of well-known photographs were thrown upon the screen, and the motive in each explained.

## Commercial & Legal Intelligence.

A HUDDERSFIELD CANVASSEER'S THEFT.—At the Huddersfield Borough Police Court, last week, Thomas Axon Lees, canvasser, Water Street, Huddersfield, was sent to gaol for a month for having stolen £10 14s. from the shop of William Phillip Pipe, trading as Mansfields, photographers, Cloth Hall Street, Huddersfield. The prisoner had been employed by the manager of the firm, and on Tuesday last, had sought to obtain a loan of 10s. from him. The money was missed the same evening from the place in which it had been secreted, and later the prisoner was arrested in Bradford with £8 in his possession.

PROFIT from Photographic Enlargements.—In the Shoreditch County Court, on the 5th inst., Mr. Alfred Mitchell, a photographic enlarger, sued Mr. Joseph Leopold Rosenschein, of Stamford Road, Dalston, a photographic enlarger, to recover £44 17s., the balance said to be due on the profits derived from running one of the defendant's branches. The plaintiff said that it was understood he was to have £2 a week. Out of the gross takings the working expenses were to be deducted, and from the balance a further 40 per cent. for cost of production and incidentals on behalf of Mr. Rosenschein. The balance was to be equally and incident as on behalf of Mr. Rosenschein. In eight and a half months the business done was £848, with working expenses £375. This left £503, out of which 40 per cent. had to be taken, leaving, roughly, £302, plaintiff's half being £151. Of this he had only received £106, and he now claimed for the balance. Counsel (to plaintiff): Your price for the enlargement was 16s. 11d. What was the actual cost to produce?—Three shillings, the frame and glass completed. The defendant, Mr. Rosenschein, was called, and said that the agreement was that the 40 per cent. was to be deducted from the gross takings, which would mean that the plaintiff actually owed him £22, which was counterclaimed for. He was certain that every picture cost them 12s. Proofs of the photographs, he added, cost 8d. each, and they only got 30 per cent. good ones. Glasses cost 6d. each, first cost, and 15 per cent. were broken in transit from Germany. Plaintiff's counsel: Where do the frames come from, and what do they cost?—From Germany, and cost 3s. each. I suggest you have bought some for 2s. 4d., others at 2s., whilst some even as low as 1s.—I don't think so low as 1s., but I might have done at 2s. Eventually Judge Smyly said that the plaintiff was bound by his agreement, and found for the defendant, whom he awarded £22 on his counterclaim.

WRONGFUL Dismissal.—Recently in the Official Referees' Court, London, Mr. Muir Mackenzie, Registrar, delivered judgment in the case of Plummer v The Brighton Palace Pier Company. The action, which was for damages for wrongful dismissal, and an account, was reported on p. 576 of the B.J.P., July 20, 1906, at Lewes Assizes, when the jury gave a verdict in favour of the plaintiff. The case now came before Mr. Mackenzie for assessment in damages. It was alleged that the contract, which was dated June 19, 1903, provided

that the plaintiff was to be the manager of certain photographic shops on the pier. Some of the clauses in the contract provided that certain expenses were to be deducted out of the receipts, and that plaintiff's remuneration was to be 50 per cent., and that he was to give the whole of his time to the business. In dismissing the plaintiff, the defendants gave him a fortnight's notice, and Mr. Mackenzie now decided that the contract was one of hire only, and not one in which the expenses could be deducted. Altogether he gave judgment in favour of the plaintiff for £250 12s. 1d.

**THEFTS from Photographers.**—Before Mr. Horace Smith, at the Westminster Police Court, Lewis Gale (27), of Ely Place, Clapham Road, and Robert William Macey, of Adeney Road, Fulham, were charged (on remand) with stealing a cash-box and its contents (about £8) from Messrs. Norton and Gregory, Limited, photographic printers, of Castle Lane, Westminster. The prisoners were each sentenced to three months' hard labour.

At the Clerkenwell County Court last week, Thomas Lee, painter, was charged with stealing at 10, Upper Street, Islington, a life-size photograph of the value of £2 10s., the property of Edward Sharp, a photographer. The prosecutor said that he was at the back of his shop when his attention was called to the fact that a picture had been taken—an enlargement. Prisoner was seen to be walking down the street with it. The prisoner said that he was very sorry. He had been drinking. He was sent to gaol for six weeks.

At Newton Abbot, last week, Arthur James Freeman, draper's assistant, about 30 years of age, was charged with stealing a three-quarter plate camera and accessories, value £6, the property of Thomas Cann, photographer, of Bovey Tracey, on November 15. Accused was committed for trial.

#### NEW COMPANIES.

**PHOTO REPRODUCTIONS.**—£1,000 (£1). To acquire the business of a photographer and photo-engraver carried on by S. W. B. Vines at South Parade, Nottingham, and the business of a collotype printer carried on at Sherwood Street, Nottingham, as the Electric Photo-Printing Company. No initial public issue. First directors (not less than two nor more than five): S. W. B. Vines, A. Hutchinson, W. H. Kirkland, and F. V. Barnes. 100, North Sherwood Street, Nottingham.

**FULTON SYNDICATE.**—November 24. £1,000 (£1). Photographers, engravers, etc. No initial public issue. Registered without articles. Worcester House, Walbrook, E.C.

**CAMERAS, LTD.**—Registered November 27. Capital £2,000, in £1 shares. Objects: To carry on the business of manufacturers of and wholesale and retail dealers in cameras, lenses, slides, shutters, and other photographic apparatus, etc. No initial public issue. Registered without articles of association.

## News and Notes.

**THE Proposed Photographic Exhibition at Dresden.**—A preliminary meeting to discuss the arrangements for this international exhibition was held at Dresden on November 29 under the chairmanship of Herr Finanzrat Beutler. The meeting was attended by about thirty gentlemen representing photographic interests in all parts of the German Empire. After considerable discussion it was decided that the year 1909 would be preferable to 1910 for the holding of the exhibition. The opinion was expressed that no means should be omitted to make the exhibition fully representative of photography in all lands, and that to this end the separate departments of photographic industry, science, and art as practised in various countries should be included in the scheme of the exhibition. It is proposed to issue invitations in reference to the exhibition early in 1907.

**STREET-BETTING Photographs.**—There were no less than thirty-six betting cases at the St. Helens Police Court one day last week. The Chief Constable said the number of street-betting men in the town was simply appalling. To get at the offenders the police had

to evade a cordon of watchers. Men, women, and children took part in the betting, surrounded by quite an army of scouts, and it was extremely difficult for the officers to get near them. On this occasion, however, they had got right into the camp and had taken photographs of the betting in progress.

**ROYAL INSTITUTION.**—The following are the lecture arrangements at the Royal Institution, before Easter:—Mr. W. Duddell, a Christmas course of six experimentally illustrated lectures on "Signalling to a Distance; from Primitive Man to Radio-telegraphy," adapted to a juvenile auditory. Professor Percy Gardner, two lectures on the sculpture of Aegina in relation to recent discovery; Professor A. C. Seward, two lectures on survivals from the past in the plant world; Professor W. Stirling, six lectures on the visual apparatus of man and animals; Dr. W. N. Shaw, two lectures on recent advances in the exploration of the atmosphere; Major P. A. MacMahon, two lectures on the standards of weights and measures; Professor W. W. Watts, two lectures on (1) the building of Britain; (2) recent light on ancient physiographies; Dr. W. Martin, two lectures on old Dutch painting and painters; Dr. C. W. Saleeby, two lectures on biology and progress; Sir Alexander Mackenzie, two lectures on latest phases of music (with musical illustrations); and Professor J. J. Thomson, six lectures on Röntgen, cathode, and positive rays.

A DEMONSTRATION of the chrono-megaphone was given at the Hotel Cecil, on the 6th inst., by Messrs. Gaumont and Co., of Cecil Court. This instrument is a combination of the cinematograph and the chronograph, and the perfect synchronism between the pictures and the sound is very marked. The greatly increased sound is obtained by using a motor, which pumps compressed air through the trumpets, so that the volume may be adjusted to the size of the hall. Several of the selections were extremely good; whilst others, doubtless from the nature of the hall, were characterised by the peculiar nasal metallic twang which we are familiar with. The films were hand-coloured, and doubtless the exhibition which is now being given daily at the Hippodrome will create considerable interest.

**MESSRS. J. H. DALLMEYER, LTD.,** announce that they are showing a choice selection of portraits taken with their well-known lenses by leading American and Canadian photographers. Pirie MacDonald, Dudley Hoyt, Notman, and many other celebrated workers are represented, and the whole collection is eminently "sane," while being most artistic in character. The framing is very tastefully done, and should afford some useful hints to would-be exhibitors. The Exhibition opens to-day, and the pictures will remain on view from ten till four till the end of January, admission free.

**THE Convention Social Evening.**—This function, so much enjoyed last winter, will be held for the second time in the gallery of the Royal Society of British Artists, Suffolk Street, Pall Mall, S.W., on Friday, January 11, 1907. The programme will consist of a reception by Mr. E. J. Humphrey, president, a selection of music under the direction of Mr. F. A. Bridge, and a "little dance," with Messrs. Alfred Ellis and Walter Potter as M.C.s. Mr. Bridge will supply tickets for members' friends, and application should be made to him at East Lodge, Dalston Lane, N.E.

**THE United Stereoscopic Society.**—In reference to the letter from M. Victor Selb, in our last issue, Mr. A. J. Snow, Secretary of the above Society, writes to us from 74, Lloyd Road, Walthamstow, as follows:—"During the next few months a series of demonstrations and competitions on criticism, toning, trimming, and mounting stereoscopic prints have been arranged amongst the members of the Society. I am also arranging a special set of our members' slides to send on a tour amongst the stereoscopic division of the International Photographic Exchange of America. This special set will then be circulated over a stereoscopic society forming in Australia and New Zealand, thus giving our English members an opportunity of corresponding and exchanging prints with stereoscopic workers in other countries. I shall be pleased to answer any inquiries respecting our Society from your readers interested in stereoscopy."

**USERS of "Challenge" cameras** should make a note of Messrs. Lizars' competition, which closes on January 10, 1907. As previously announced in our columns, the money prizes to be awarded amount to £200, which sum is divided into 87 different sums, so that competitors of all classes should be assured of a fair chance to win an award. The judges are Sir John Ure Primrose, Sir Francis Powell, and Mr. C. F. Inston.

## Correspondence.

\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
 \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE POSTCARD TRADE.

To the Editors.

Gentlemen,—This is, without doubt, an age of cheapness. But the general public expect quality as well as quantity. The difficulty is, how to fulfil the two requirements. Can we anticipate photography becoming a necessity instead of a luxury? For there can be no denying it is a luxury at present. Has the price anything to do with this? If so, will the decrease in price increase the demand? I am prompted to these remarks by the frequent request by customers to be photographed for picture postcards. Now, the person has in mind the cheapness of postcards when making this request. They wish to be photographed, but wish to have it done cheaply. I am only a country professional, and the town and district not a very large one. I have worked it out, and find that if I have two sitters every day in the year this will mean twelve per week. These at 5s. per dozen will yield me £3, or at 3s. 6d. £2 2s. But I also find that in about three years I shall have photographed every man, woman, and child in the town—that is, assuming the place to keep at its present population. Is it possible that all these will come to me, or that if they do not that sufficient of the others will give me resittings to make up for the want of the others?

Then there is another side to this question. Can I conscientiously ask two and a half times as much for finished cabinets when the unmounted postcard is almost equal in size, and receives the same amount of work. In fact, the only difference is, the postcard is unmounted.

Again, in some places I hear 2s. per dozen is the price asked, "and excellent photographs they are," is the comment.

Up to the present I have discontinued the portrait postcard trade, the demand becoming more persistent, I am questioning if an all-round price of, say, 5s. per dozen and 2s. 6d. for the second dozen would help to make photography a necessity.

I should like to hear the opinion of some who are working the postcard trade, giving the best value—no second or third rate work.  
 —Yours truly,

PORTRAIT POSTCARD.

### THE R.P.S. AS AN ADDRESS.

To the Editors.

Gentlemen,—The address attached to my name as Secretary of the above Society, in the extremely valuable directory of societies in your "Almanac" for 1907 is a private address for private communications only. I would be glad if you would allow me to ask correspondents to address all club communications to the address given as "Club Headquarters," the Polytechnic, Bedford Park, W. I am, yours respectfully,

A. G. FIELD, Secretary Acton and  
 Chiswick Polytechnic Photographic Club.

December 10, 1906.

[The address in question is that of the Royal Photographic Society, 66, Russell Square.—Eds., B.J.]

### SULPHIDE TONING.

To the Editors.

Gentlemen,—In reply to Mr. Thorne Baker's letter on the above subject in your last issue, I would say that it seems to me quite impossible that sub-bromide of silver should be formed when bromide prints are bleached in pure ferricyanide solution. For neither in the matter bleached nor in the bleacher is the element bromine present.

I take it that when ferricyanide solutions free from admixed alkaline bromides are used as bleaching agents, the product formed is white silver-ferricyanide. For if the action is allowed to proceed to completion the prints are in these cases literally bleached—the images become invisible.

The solutions of ferricyanide I used in my experiments had a concentration of close on 4 per cent., and I found that prints had to lie in such solutions for several hours before the bleaching was com-

plete. As I stated in my paper, the tone obtained by sulphuretting prints thus completely bleached did not appeal to me, but *de gustibus non est disputandum*.

It may be of interest to note that a print thoroughly bleached in potass ferricyanide, behaves in quite a different manner from one treated with ferricyanide + alkaline bromide when the treated prints are exposed to bright sunlight. In the former case an image appears which is generally a rusty yellowish-brown; but this image is faint and does not nearly attain to the intensity of the original bromide print. In the latter case, on the other hand, the sub-bromide image is rapidly darkened to an intensity differing but slightly, if at all, from that of the original print. The tone of the picture thus obtained by mere bleaching in a bromide bleaching solution and then subsequent insolation might possibly suit some subjects or appeal to some tastes.

DOUGLAS CARNEGIE.

Newcastle-on-Tyne.

### 'PHOTOGRAPHIC ASSISTANTS' PROTECTIVE SOCIETY.

To the Editors.

Gentlemen,—Up to the time of writing, seventeen names have been sent to be placed on the list towards the above Society. The above number consists of five ladies and twelve gentlemen. Ten others have made inquiries as to whether their names will be published in the "Journal." All letters and names are quite confidential, and will not be published. If the Society does not become strong enough to support itself all letters will be destroyed. Will the ten kindly give me permission to append their names to the above numbers; also any suggestions will be welcomed. A great number have asked questions regarding the same. Those who have not received a reply will have one in due course.

Out of the seventeen who have definitely sent their names, only four have sent suggestions, which I give in the following order:—

1. That an Assistants' Society be formed with the object of assisting the P.P.A. in every possible way to brighten the career of assistants.

2. That a Society be formed to petition the P.P.A. to have a central studio and rooms for assistants to go direct to pass all examinations, as the present method of testimony of present and former employers is disliked by many, owing to their present employers not being members of the P.P.A., the assistants being in favour of the P.P.A.

3. A Society of Assistants be formed to work in accord with the P.P.A. That we ask the P.P.A. to publish at a reasonable price an "Assistants' Quarterly," giving the names of those who successfully pass examinations, and other information which will encourage assistants of all grades to take up the cause. The leaders of the P.P.A. could then write articles on professional photography and the assistants generally; this would give them more heart.

4. The only suggestion I can make is this: That the assistants form a Society, and publish a monthly review, giving all experiences of different things that occur in the different spheres of work. Also to give every assistance to the P.P.A. in furthering the good work they are trying to accomplish.

Now that a good number have ventured to tackle the problem, perhaps those who have hung back waiting to see the result will now send their names and any suggestions. One point which is very evident in the letters is that the P.P.A. is evidently well respected generally, and a great many are hanging back from it through no cause at all.—Yours faithfully,

19, Richmond Terrace, Romsey, Hants.

U. DOUSTR.

### THE CANVASSING FRAUDS.

To the Editors.

Gentlemen,—I beg to call your attention to the enclosed cutting from the "Central Somerset Gazette," Glastonbury, December 8, 1906. The "free portrait canvassers" have been working this district for some weeks past, giving an address at Weston-super-Mare as their headquarters.

I know of one case in Glastonbury where a gentleman allowed them to make two "free enlargements," which were ultimately brought home ready framed in German gilt, 50s. being the price asked—and well-nigh demanded—for the pair of frames. But in the meanwhile I had called the gentleman's attention to some recent issues of the B.J., with the result that the enlargements were removed from the frames and kept, and the frames refused. I

brought this to the notice of the representative of the local paper, and the enclosed cutting is the result.—Yours truly,

High Street, Street, Somerset, F. HIGDON.

[The paragraph referred to by our correspondent runs as follows:—"Complaints have reached us from some of our readers, who allege that they have been victimised by persons carrying on the 'free portrait swindle.' This is apparently the same gang whose operations have been exposed in other parts of the country, and we counsel our readers to be on their guard and to have no dealings with these plausible canvassers. If proposals are made to them to participate in backdoor transactions of this nature the best course for our readers to pursue will be that advocated by the 'Llangollen Advertiser,' who in a similar instance recommended its readers to close their pockets, open the kennel door, and let the house dog do the rest."—Eds., B.J.]

#### WASHING POSTCARDS.

To the Editors.

Gentlemen,—I observe from your issue of the 7th inst. that "A Country Postcard Printer" has not been succeeding to his satisfaction with the method of washing postcards described in my article on postcard printing ("B.J.P.," September 14, 1906). The question he raises is so obviously one of manual dexterity that there is bound to be wide differences with various workers, and my object was not to set a time limit, but to describe an efficient and quick method of washing. This I still think was done. I find from my workroom notebook that the total time of toning, fixing, and washing postcards in the manner I described averages three hours for two gross, with assistance in washing, to four hours single-handed. These times are very constant for a number of entries ranging over eighteen months. When writing the article I allocated, as I thought, a sufficient portion of this time to the washing, but there is no doubt that I gave too much time to the toning and too little to the washing. From actual experiment I find that washing after the manner I described occupies seventy to seventy-five minutes. *Per contra*, the time occupied in toning is very much less than I had imagined it to be, hence the net result remains the same.

Of course, it is impossible to lay down hard and fast rules in a matter of this kind, so entirely dependant on individual expertness. Your correspondent appears to be giving an excessive amount of time to draining if he only records two dozen per minute. It is when leaving the fixing bath and the first two or three washing waters that deliberate draining is necessary; after the first squeezing the surface "hypo" is largely eliminated. I would strongly recommend your correspondent to use the permanganate test, and be guided by its indications.

I have not tried "A Country Postcard Printer's" method of pinning each card to a cork, and I am afraid that at present I have not sufficient leisure to do so, but I incline to the opinion that with a little practice he would find the method I described quite as simple and certainly quite as quick as his own.—I am, gentlemen, yours faithfully,

G. T. HARRIS.

Sidmouth, December 9, 1906.

To the Editors.

Gentlemen,—Your correspondents who are in trouble over the washing of postcards may be interested in my method of handling batches of from 600 to 1,000 of toned P.O.P. cards. I use large domestic baths with a net stretched over a stout wire ring fitted about four inches from bottom. The water is running throughout the toning, and each card as toned is thrown under the tap, which rinses off all adhering solution.

I tone 50 to 70 at a time, and I turn over the cards in the baths thoroughly every ten minutes or so. When about 300 are in one bath I put a syphon on to bath No. 2, and so on. By the time I have filled bath No. 3 the cards in No. 1 are nearly ready to come out. I squeeze and place on special racks to dry, and flatten by pressure afterwards. On an average four hours is amply sufficient for handling and finishing 600 cards. I have had little trouble in obtaining permanency sufficient for commercial purposes. (I enclose card over fourteen months old.) In using combined baths, it is essential that two deep dishes should be used for quantities, passing cards rapidly from one to the other. Over-toning can then easily be checked.

It is only occasionally that I get a spoilt card in a batch since I worked on the above lines.—I am, yours faithfully, F. NEWELL.

Manningtree,

[The card enclosed certainly speaks well for this method.—Eds. B.J.]

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

Starr & Rignall, 108, Fitzroy Street, Cambridge. Three photographs of Dr. Stubbs Bishop of Truro.

P. Wynne, 518, Coventry Road, Small Heath, Birmingham. Photograph of the Birmingham Football Club, Season, 1906-7.

W. McCrae, 14, Berkeley Road, Dublin. Photograph of the Mater Misericordiae Hospital, Dublin.

C. C. Bedford, Carr Street, Ipswich. Two Combination Photographs Containing altogether 16 views.

OWING to great pressure on the "Answers to Correspondents" column this week a number of replies are unavoidably held over.

F. M.—You are evidently confusing several lenses. Those shown at the Royal Photographic Society—we believe they are still to be seen there—were taken with the Pulligny lens. The lens to which you apparently refer gives very similar results, but we have no experience of the anastigmats. Your best course is to write the agent, stating, more clearly than you have to us, whether you require a lens for artistic work or critical definition.

FLASHLIGHT, ETC.—A. Please publish a formula for flash powders suitable for dinners, at homes, etc. B. Is it possible to photograph a group on a theatrical stage without extra lighting, using rapid isochromatic plates and *f*/6.3 anastigmat lens? What would be the necessary exposure? Is a so-called green sensitive plate suitable?—OLD PRO.

A. As a rule nothing but pure magnesium is used, which is blown through a spirit flame. A simple formula is—

Potassium permanganate ..... 3 parts.

Magnesium powder ..... 4 parts.

Powder the permanganate, and then mix carefully with the magnesium without rubbing; 60 grains of this will give an exposure of one-tenth of a second. Considering the number of satisfactory commercial powders, it is hardly worth while mixing. B. It certainly is possible, and full details will be found in our issue for July 6, 1906, p. 529. The green sensitive plates are not so suitable as those described in the above article, or the newer panchromatic plates prepared with isocyanines.

GEO. ROSS.—We have no record of the addresses of the two companies. You could find out by application to the Registrar of Joint Stock Companies.

M. BARNARTT.—You could probably obtain them from Marion and Co., Soho Square, W., or Jonathan Fallowfield, Charing Cross Road, or a wholesale artists' colourman like Newman, Reeves, or Barnards.

BOOK ON COLLODION EMULSION.—Can you tell me through your columns where I can buy a first-class, up-to-date volume on making collodion emulsions for three-colour work, or give me

formulae for same, including sensitisers and developers? I have Hübl's work, but can find no information on the making-up of the emulsion.—A. M.

Baron von Hübl has written a special treatise on collodion emulsion, which has not been translated into English. "Collodion Emulsion," by H. O. Klein, published by Penrose and Co., would probably answer our querist's purpose.

**SAFE LIGHTS.**—Some two (perhaps three) years ago there was published a formula for staining the gelatine on plates to make them of use for light-filters for ordinary photographic work. The dyes recommended were aurantia, eosine blue, rhodamine, and tartrazin. I have looked through my bound numbers of the B.J. and Almanac, but cannot come across it. I tried it at the time, and stained two films, one a bright yellow and one a bright red. I have recently had the misfortune to break one of the lights of my darkroom lantern, and wish to replace it. Can you tell me where the information is to be found? I do not remember the strength of the solutions.—J. E. GUBBINS.

We are also unable to trace the particular formula, and probably it was given in some article or paper incidentally. There should be no difficulty, however, in making a red screen from the dyes mentioned, assuming that they are already in stock, and soaking the plates in—

Tartrazine .....	10 grains.
Rhodamine .....	5 grains.
Water .....	2 oz.

will give a good red filter. We prefer reducing the rhodamine to one-fifth of the above, and using a second screen dyed with methyl-violet; this gives an intense red which is very safe. See also "B.J. Almanac, 1907," p. 975.

**ACID BISULPHITE.**—In the "Almanac" for 1907, p. 789, occurs "acid bisulphite (com. liq.)," and on p. 757 "acid sulphite lye," which I presume means the same. The druggists here do not know it. Can you tell me what it is, and where it can probably be procured?—C. E. F. N.

The terms are synonymous, and refer to the commercial solution of acid sulphite of soda  $\text{NaHSO}_3$ , which is very largely used in dyeing, wood pulp manufacture, etc. There should therefore be no difficulty for any chemist to obtain it through his wholesale house. Care must be taken, however, to specify the lye and the degrees Beaumé, as the dry salt is not so stable. The lye can be obtained from the Lumière N.A. Co., 4, Bloomsbury Street, W.C.

**ANXIOUS.**—The whole thing depends upon whether you have any agreement, etc., and the only thing we can recommend you to do is to consult a local solicitor. It is impossible for us or anyone else to advise you without knowing all the facts as to the agreement, whether the person who sublet to you had any right, and so on.

**SULPHOCYANIDE TONING.**—1. Can you assist me in solving a toning difficulty? Gelatino-chloride P.O.P. prints, toned in bath in following proportions,

Gold chloride .....	1 gr.	} Mixed and used at once
Amm. sulphocyanide 10 gr.		
Water .....	7½ oz.	

instead of passing from red to purple, take a nasty yellow colour, and, if taken further, arrive at a bleached blue-grey. The lower the temperature of the bath the worse is the effect. 2. Does the use of electric light for printing purposes necessitate any modification of the toning-bath? I understand that electric light has a somewhat different effect upon the silver chloride from daylight. Would this influence the toning?—PRINTER.

The trouble is entirely due to the bath being used at once. When mixed with cold water, auric sulphocyanide,  $\text{Au}(\text{CNS})_3$ , is formed, and this acts in toning with the formation of silver sulphocyanide in which 3 of silver replace the gold. If the bath is allowed to ripen, then aurous sulphocyanide,  $\text{AuCNS}$ , is formed, and only 1 of silver has to replace the gold. The trouble may be got over by dissolving both salts in boiling water and allowing to cool, or by dissolving in a small quantity of water, boiling for five minutes, and then adding the rest of the water. The bath can then be used at once without the recurrence of the trouble. 2. No. The electric light, in consequence of its richness in violet

and ultra-violet rays, may affect the silver chloride more than the organic silver salt, and there may be therefore less contrast in the print, but as regards toning, there is no effect.

**PHOTOGRAPHING MACHINERY.**—I enclose a cutting from an advertisement of an engine. I will be very glad if you will reply to the following:—1. How is the outline of this photograph softened, or background darkened? 2. How should one set about photographing machinery for catalogue purposes (plates, developer, etc.)? 3. What is the best way to subdue reflections from polished surfaces? 4. Are there any books on "Photography of Machinery"?—A. WILSON.

1. The shading, if thought desirable, may be done with the air-brush, the machinery being photographed with a very light background. 2. Use ordinary plates and developer, such as you are accustomed to. 3. By coating them with the colour, given on p. 997 of the "British Journal of Photography Almanac," just issued. It would be best to coat the whole of the machine with the colour before photographing it. 4. No; there is no book devoted to the subject.

**DRYING NEGATIVES.**—I recently put a negative up to dry when the weather was very damp. After about thirty-six hours I looked at it and only the edges were dry. About that time the weather became brighter and dryer and the negative soon dried, but on examining it again I found that the part that had dried first was not so strong as the centre which had dried more quickly. This is, I believe, a well-known phenomenon. Can you tell me: (1) The cause; (2) the means to prevent; and (3) the remedy for this state of affairs.—H. J. L.

1. The cause of this phenomenon has never been accurately determined, though Liesegang proved many years ago that when a negative was dried by heat it became denser, and he ascribed this to a closer aggregation of the silver particles. 2. The means to prevent are either to dry in a draught or in a warm place such as a mantelshelf over a fire. Or the negative may be immersed in methylated spirit for five or ten minutes, and then it will dry very rapidly near a fire. 3. It is almost impossible to even the marks out when once they occur.

F. M. W.—We have never made any such offer. Something of the kind is offered by the Professional Photographers' Association. Better address the Secretary at 89, Albany Street, London, N.W.

**GLAZING POSTCARDS.**—I should be extremely obliged to you if you could inform me by what process the glazing of collotype postcards is done. 1. Are they done by gelatine, or by using a solution of shellac bleach and borax? I should be pleased if you would give me some details of a practical method. I have seen several cards glossed and have peeled off the film, but it appears too tough to be only gelatine, or otherwise it is thickly coated. Would it not be possible to coat these cards straight off the machine, as the ink is greasy, and it would be a job to get the gelatine solution to flow evenly without the use of plenty of spirit? 2. At the same time, could you give me the address of the Photographic Novelties Syndicate, Limited?—Geo. Ross.

1. Postcards are glazed by floating on the borax shellac varnish sometimes; but the film sent is obviously gelatine, and is probably obtained by squeegeeing the cards after printing and when the ink is dry on to sheets of glass, which have been previously waxed, and which are coated with a 5 or 7½ per cent. solution of gelatine containing a little chrome alum or formaline. If a 5 per cent. solution of gelatine is used, with about 5 per cent. of the total weight of gelatine or formaline added, this should answer the purpose. 2. We do not know the address.

**STUDIO RENT.**—I would be very much obliged if you could give me any information on the following, as I am entirely at sea in the matter. I have for some two years been renting a photographic business, the studio having been standing and used as such for a few years by the owner without having been called upon to pay rates for same. I had it rented from the owner for two years, and was told by him they could not claim rates upon a place used for that purpose, as a photographic studio was classed as a workshop, and during the time I had it I was not called upon to pay any rates whatever. This last summer, the owner of the studio wished to have the sole use of it for a cycle repairing shop, so I had to give it up. But a friend of mine got one erected on

the same piece of land on which the other studio stands (now used as a cycle shop), so that the two erections are standing side by side on land rented by the owner of cycle shop. I still have the photographic business rented of owner of cycle shop, and therefore pay no rent for the ground on which the studio stands. The owner of cycle shop pays that. Now, I have been called upon by the local authorities to pay rates assessed at a rental of £5. The photographic studio only cost altogether £17. I have agreed to pay my friend a rental for studio equivalent to a 10 per cent. on the cost of studio, which will come to about £1 15s. a year. What I would like to know is: Can I be compelled to pay rates on a photographic studio, and if so, can they claim on what they think—i.e., £5, or only on the actual rent I pay?—W. A.

It is an open question whether a studio is a workshop in the strict legal sense, as it has been held that it is, and also the other way, too. The usual custom is that the rates are assessed on the actual rent, and your only plan is to appeal to the local assessment committee against the assessment and state fully your rent.

**WASTE PIPES.**—I have been very troubled of late through the waste pipes in my printing room sinks becoming choked. Practically the whole of my printing is carbon, and the arrangement I have is three large earthenware sinks—one for the tissue, one for the temporary support, and one for the alum. I have also fixed a hot-water sink for the developing. The waste for these different sinks all runs into one large 2-inch waste pipe. I find that periodically this pipe becomes coated and choked up with a curious mixture that seems to be alum and gelatine, so that the work is stopped completely. I have tried cleaning the pipes with strong soda water, but this seems to have little effect, and should be glad if you could let me know of anything which would effectually clear them out.—DARK ROOM.

No doubt the compound is gelatine in some form, and the best thing to remove it is boiling water, allowed to act on it for some time, and then one of the domestic rubber force cups, which can be obtained from any ironmonger. After the work is done every day hot water should be run through the pipes for some time so as to clear them.

**ENLARGING LANTERN.**—I have made, upon popular models, an enlarging lantern with 11-in. condenser, and, as far as I can make out, is made properly, but upon lighting up and focussing for a disc of white light upon the screen I get a semi-black disc of the same size as the white disc would be, with a small halo of white light with reflection of gas mantle and reflector in centre. I have tried ground glass interposed between condenser and source of light, and moving light to and from condenser, all to no purpose. I cannot get a white disc of light at all. Do you think the fault lies in the plano-convex condenser, as looking through condenser you can see the gas mantle and reflector quite clearly, instead of the white bullseye of light, which I presume ought to be? Kindly advise me on the matter, as the lantern, etc., seems all right, and I do not know whether the fault lies with the condenser or my handiwork.—F. O. WATTS.

The black centre is due to the distance between the light and condenser being wrong—probably too near. With condensers of such large aperture the focus would be some distance away. The only thing is to shift the light to and fro till a perfectly even disc is obtained. The image of the mantle cannot be avoided, and some diffusing medium, such as the finest ground glass, must be used.

**WET COLLODION TROUBLE.**—Will you kindly inform me how to overcome streaks on half-tone negatives (wet process) caused by alcohol running down the plate in lines during exposure? The plates are well drained before put in the dark slide. I have tried evaporating the silver bath, but after being in use a day or so they appear again as bad as ever. I find putting alcohol in the developer no remedy. The strength of my bath is between 32 and 40 grs. to the ounce.—ALCOHOL.

We scarcely understand what you mean by "alcohol running down the plate." We presume you mean the bath draining down in streaks. That it is very prone to do if the collodion is very new or of a horny character. The best way of avoiding the trouble is to use a collodion that has been iodised for some time—say a few weeks—allow it to well set before the plate is put

into the bath, and then move it about while in the solution so as to remove the solvent in the collodion as much as possible. Then drain well before putting the plate in the slide. Your bath is unusually strong; from thirty to thirty-five grains to the ounce is ample.

**SENSITISING CARBON TISSUE.**—Are there any substances other than the chromates and bichromates that may be used for sensitising carbon tissue?—F. B.

No. Not to be of any use.

At the recent Milan Exhibition Messrs. L. and C. Hardtmuth were awarded against all comers the Grand Prix for their pencils.

**THE Scottish Portfolio.**—This favourite circulating exhibition again "on the road" round the Scottish societies. From the 2 prints submitted to him Mr. Alex. Keighley, Keighley, Yorks, selected 98 to form the portfolio, but he has been unable to select one as winner of The Macdougald Plaque (a specially designed plaque gifted by last year's president of the Scottish Federation) the best picture entered for the Portfolio. He has placed two prints (both figure studies) equal first—viz., "A Sleepy Story," by Murray, Barrhead; and "A Study in Gum," by A. W. Hill, Shot the energetic Portfolio secretary. In a lengthy criticism on the entries, Mr. Keighley, amongst much interesting matter, gives the following definition of a perfect negative:—" . . . . The relative tones (i.e., degrees of light and dark) are dependent on the time of exposure and the sensitive plate. By giving a subject, say, half a dozen different exposures on separate plates, as many different renderings of the same subject will result, one of which may be truer to nature than the rest. This, and this only, is the perfect negative; the rest, however "plucky," sharp, clear, etc., are wrong. It is a useful practice to compare the print with the original scene and to notice if the values are right." The Portfolio, in its tour round the societies, is accompanied by a magazine in which may be recorded the opinions and criticisms of those who view the exhibition. To the society situated remote from the populous centres this Portfolio will form a welcome feature in club life and give the members an educative glimpse of what other folks are doing, and the glimpse will be more satisfactory than many reproductions in the press, if they see the actual photographic print unaltered by any half-tones block.

**MR. SYD. SAWYER**, whose photographic work has long been known for its excellence, particularly in group and genre work, has now broken out in a new direction, and on Monday, the 17th inst., at the Scala Theatre, a new one-act humorous play will be presented by the Wyndham Dramatic Club as a prelude to the "Red Lamp."

**THE Eastman Kodak Company of New Jersey.**—The usual quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding preferred stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding common stock, have been declared by the Eastman Kodak Company of New Jersey, payable on January 1, 1907, to stockholders of record on November 30, 1906.

"HOUGHTONS QUARTERLY" for November, just to hand, is a bright got-up number, with seasonable announcements and offers.

**\* \* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Members of the Croydon Camera Club visited Messrs. Wratten and Wainwright's plate factory recently. The report of this interesting inspection appears on page 1004.

The Lumières have published particulars of new "sulphited" developers. (P. 1007.)

A quick-change movement for focussing-screen and dark-slide is among the patents of the week. (P. 1014.)

A number of points connected with the effective production of stereoscopic prints are discussed on page 1002. Stereoscopic workers are recommended to devote greater care to correct orthochromatism of their negatives.

The conclusion of the paper on measurement of shutter speeds appears this week. It will be followed in our next issue by the discussion. (P. 1009.)

A rocker for the dark room is recommended by a German worker, who publishes details of the one used by himself. (P. 1012.)

The London Camera Club.—Proposals for the immediate occupation of club premises are announced. (P. 1015.)

In the course of an article on page 1005, Mr. F. Dundas Todd outlines a system which professional photographers should apply, with modification which may be necessary, to their own businesses. (P. 1005.)

A case was heard in the Court of Appeal last week in which compensation for injury to a chemist under the Employers' Liability Act was withheld. The chemist, according to the ruling in the Appeal Court, was not a workman. (P. 1002.)

## EX CATHEDRA.

### Pyro-ammonia.

The evergreen subject of development was on the programme of the Croydon Camera Club last month, and Mr. H. W. Bennett once more seized the opportunity of praising pyro-ammonia, which at one time was a much favoured developer of our own. He is, however, reported to have said that it does not oxidise so rapidly as pyro-soda, and if the report is correct one must differ from this conclusion most emphatically. For the production of clean, unstained negatives pyro-ammonia is not to be beaten, but for the production of a greasy mess of oxidised pyro in the shortest possible time it is unequalled. We never met with a pyro-ammonia developer that could be used with any satisfaction for two plates in succession, while we often use pyro-soda for three or four, and have used it for six, with perfect success. As regards results, there is little fault to find with pyro-ammonia, and for making the best possible negative from a bad case of over-exposure it is unrivalled. Owing, most probably, to the volatile nature of the alkali, it is the ideal developer for over-exposure, and an exposure of thirty times the normal can be tackled with confidence if the citrate method of restraint is adopted. As regards convenience, the trouble of keeping the ammonia solution puts the developer altogether out of count beside pyro-soda and the modern developers. It was impossible to work it satisfactorily without the aid of an hydrometer to make up and test the ammonia solution, and unless great care was taken in this respect every plate developed had to be treated tentatively, development by time being impossible. It was a difficult matter to produce two negatives exactly alike, and a risky matter to attempt the development of a number of different negatives in one dish. The smell was also a serious objection to many people. Probably the reason why the developer held its own so long was its cleanliness so far as the negatives were concerned. The early pyro-soda developers produced abominably stained negatives in various shades of brown and green, and as soon as this defect was cured pyro-ammonia was doomed.

### Photography at the British Museum.

In a recent issue the "Newcastle Chronicle" reiterates a complaint against the authorities of the British Museum in respect of the new rules, whereby a fee of 2s. is charged for photographing. Our contemporary goes on to say that the new rule will be to close the Museum against all attempts to popularise it by offering the public faithful representations of the antiquities, but it should be remembered that there is another side to this question. At one time anyone could take a camera and photograph any object he liked without pay-

ment, and, as a consequence, cameras became more or less a nuisance in the Museum, whilst the pictures obtained were never seen by the public. During the photographic operations visitors could not examine the objects. Furthermore, the attendants' time was taken up in standing by watching them if they were removed from their usual places, which was frequently the case. The new rule will not much attract professionals who have commissions to execute for publishers, as they can legitimately charge the fees to those for whom they do the work. At the National Gallery amateurs are not permitted to photograph the pictures, a rule which the late Camera Club tried to make the object of an agitation, alleging, curiously enough, amongst other arguments, that amateurs could spend more time over the work than professionals, but apparently forgetting that all that time the public were deprived of the pictures. Professional photographers can obtain permission to photograph the pictures because then they are published, and the public can get copies of them. In one instance, we are told, a foreign firm obtained some extra facilities for doing the work because it undertook to issue a certain size of the reproductions to the public at quite a nominal figure. It seems to us that the recent rule at the British Museum is by no means a bad one. The fee may tend to deter amateurs from blocking up the objects with their cameras to the inconvenience of visitors, who will never see the results, while professionals can charge the fees to their clients, and the public will have the opportunity of seeing the reproduction. After all, the fees are not exorbitant.

\* \* \*

#### Employers' Liability.

A case of great importance where services of persons of scientific attainments in certain manufactures are necessary was before the Court of Appeal last week. In brief, it was as follows: A gentleman, a master of science, of Manchester, was in the employment of a firm of manufacturing chemists, and during the course of his work met with an accident to his leg, as a result of which he died from blood-poisoning. His widow entered an action in the county court, under the Workmen's Liability Act, for compensation for the loss of her husband. The defence was that the deceased was not engaged as a workman, but as a master of science in a totally different capacity. It appeared that he had to do a good deal of manual labour, such as turning on steam-cocks, taking samples, testing, and charging pans, about five-sixths of his time being thus employed, the remaining one-sixth being spent in the laboratory. He received a salary, which was paid monthly. The judge who heard the claim held that the fact of a man being a master of science was quite irrelevant, so long as he did manual labour, and accordingly he awarded the widow £300 as compensation. The defendants appealed against that decision, and the appeal was heard last week. It was allowed by a majority of the judges, and the case sent back to be re-heard.

\* \* \*

#### What is a Workman?

In delivering judgment, the Master of the Rolls said that the employers intended to avail themselves of the skill of the deceased in his capacity of master of science and not of a workman. He was not even employed under the conditions of an ordinary workman. He started work later and received a salary. The fact that he did manual labour would not alone turn him into a workman. In order to carry out the agreement it was necessary that he should do some amount of manual work, and in these circumstances he thought the appeal should be allowed. Lord Justice Cozens-Hardy agreed, but Lord Justice Farwell dissented, seeing nothing in the facts that the deceased's hours were

different to those of the other men, and that he received a salary instead of a weekly wage, sufficient to overcome the fact that he worked five-sixths of his time with his hands, and that in his absence his work would be done by an ordinary workman. On the finding of fact, he thought the deceased was a workman within the definition, and that the widow was entitled to the Act. Here it will be seen that the judge of the county court and one of the judges of the Court of Appeal are of the opinion that the deceased was a workman within the meaning of the Act, while the other two judges were of the opinion that he was not. Though there is no direct photographic interest in the above case, it must be remembered that in photographic manufactures there are usually one or more persons who are engaged solely on account of their chemical and scientific knowledge, yet they usually have to do more or less manual labour, and the above ruling may materially affect them in the event of their meeting with a serious accident when following their ordinary avocations. There seems to be a nice distinction made between salary and wages, and between an ordinary workman and one possessing considerable scientific knowledge, which it is difficult for a layman to understand.

#### SOME MATTERS CONCERNING STEREOSCOPY

A short time ago (September 28) we gave the rule for determining the correct separation between two stereoscopic prints, but since then we have come across so many conflicting but very positive statements with regard to the matter that it is evident the rule is not well known and is seldom observed. The most prevalent idea seems to be that the distance is a fixed one, not dependent on lens separation or eye separation or construction of stereoscope, and a curious feature is that this "fixed" distance varies with different authorities from about  $2\frac{1}{2}$  in. up to 3 in. The fact that there is no fixity about the distance should be apparent from the following considerations: A fundamental and indisputable rule of stereoscopy is that the prints must be viewed under the same angle of convergence as that at which they were taken. Suppose we apply this law in the case of very far-distant objects, then it is manifest that even with widely separated camera lenses the light transmitted through the one lens is virtually parallel to that transmitted through the other, or, in other words, that the angle of convergence is 0 degrees. It follows, then, that the results must be observed with parallel binocular vision, which means that if the stereoscope is fitted with simple lenses or no lenses at all the separation of the prints must be equal to that of the eyes. Persons with different visual separation will then, strictly speaking, require differently mounted prints, though, as a matter of fact, the eye separation varies so little with different individuals that this refined adjustment may generally be left out of account. We may, however, use a stereoscope fitted with prisms instead of lenses, and then a serious variation occurs. Assume the prisms to be perfect half-lenses, the centre of each half-lens being opposite the centre of the eye. If the prints, mounted with a separation equal to that of the eyes, are examined through this prismatic stereoscope, the visual axes are not parallel as they should be, but strongly convergent, and the fundamental law of equal convergence is violated. To preserve parallelism of the visual axes the separation of the prints must be increased by a distance equal to the width of one prism, and if this is done it will be found generally that the conventional "limit" of separation is considerably exceeded. Thus if the separation of the eyes is  $2\frac{1}{2}$  in., and the width of a prism is  $\frac{3}{4}$  in., the total correct separation of distant points in the prints is  $3\frac{1}{4}$  in. The separation for

near points is very much less, and, as very distant objects seldom show in stereoscopic views, the prints generally have to be adjusted for near objects. If the rule is applied in the case of very near objects, with lenses widely separated, it will be found that the print separation is very small; it may even be so small that the prints cannot be mounted side by side. It can easily be understood that the farther the lenses are separated the greater is the angle of convergence for near objects. When the resulting prints are examined, this angle of convergency can only be reproduced by mounting the prints close together, and it follows that the wider the separation of the lenses the less must be the separation of the prints. If the mounting separation is too great—and it nearly always is made too great in the rather exceptional case of a near object being photographed with widely separated lenses—exaggerated or distorted relief is produced.

It is often forgotten that the stereoscopic relief shown by two images made from two different standpoints is greatly aided by other non-stereoscopic conditions that suggest relief and solidity, and that the illusion may be partly or completely destroyed by neglecting those conditions. It is well known that a good photograph, if viewed with one eye from the proper perspective standpoint, will show a very marked appearance of relief and solidity. This "monocular relief," as it may be called, is due simply to very perfect perspective drawing as regards form, shade, and gradation, and, if the fact that the picture is on a plane surface is not forcibly impressed upon the observer by undue roughness or shine, the illusion may be most striking. Each print of a stereoscopic pair should show this appearance of monocular relief to perfection if the stereoscopic effect of the two prints is to be perfect, but very commonly it does not, because in very few photographs is the perspective quite correct. As regards outline, there is no fault to find, for the lens looks after that branch of perspective, but the aerial perspective is very frequently all wrong, owing to wrong exposure and wrong values. A common defect that we have noted in much stereoscopic work is under-exposure. This results in a want of differentiation in some of the deeper gradations, with the result that planes really at different distances are brought together into apparently one plane. In such a case foreground dark objects appear in the stereoscope like silhouettes, and lose all rotundity. Over-exposure may give a similar effect in the case of light objects, while if any reversal exist the aerial perspective is even inverted. If the objects are familiar ones, a very bad effect may be produced, for while the outline may show that one object is farther away than another, its shading and gradation may suggest that it is nearer—two conflicting effects that spoil the result altogether. Then, again, if the values are wrong, a similar conflict of impressions may exist. Assume the existence of two objects of different colours—say, red and blue, but of the same luminosity at one particular distance. If the red is removed to a greater distance it will appear lighter than the blue; while if the blue is farthest away it will appear lighter than the red. If, however, no attempt is made to secure correct values by orthochromatic methods, the red will appear darker than the blue even when much farther away, and, provided the true relationship of the two colours is known, a false effect of relative distance is produced. We fear that orthochromatic methods are greatly neglected in stereoscopic work, and that the extreme importance of true representation in all respects is not fully realised.

Many people have stated that a stereoscopic effect can be produced by examining a pair of precisely similar prints in the stereoscope, while many others have not only denied this, but have stated that no effect of relief at all can be

observed. In order to get at the facts of the matter, we have experimented a good deal in this direction, and find that the explanation of these varying opinions is a fairly simple one. If two similar prints, quite perfect in drawing and gradation, are trimmed exactly alike and mounted like a stereoscopic slide, the same relief is observed in the stereoscope as is visible in the case of one print examined from the proper standpoint with one eye. The effect is, perhaps, somewhat more realistic, owing to the use of the two eyes, for we are more accustomed to use both eyes together, but it is no greater. Moreover, people "blind to form"—and there are many such—fail to see the relief in either case. If, however, we trim the prints stereoscopically in accordance with the law of convergency, so as to introduce real stereoscopic relief between the plane of the mount and that of the prints, a somewhat striking effect may be produced. The mere fact that the subject is seen either in advance of or behind the mount at once suggests to the mind that the subject itself must be solid, or have rotundity and relief, and if there is no bad perspective or defect that militates against this impression, a positively startling effect may be observed. Many persons who can see no appearance of relief in a single photograph, or in two trimmed similarly, will at once see the effect in the "semi-stereoscopic" slide, though a few who are rather more absolutely "blind to form" will fail. Such semi-stereoscopic slides will be passed as fully stereoscopic by many people not in the secret, and this fact has not infrequently been taken advantage of by unscrupulous traders. Many curious and interesting experiments may be made on these lines, and we possess a number of experimental slides made up in this way that gives us nearly as much pleasure in examining as orthodox fully stereoscopic pairs. It is worth while specially looking out for prints suitable for the purpose, for an important lesson may thereby be learned. It will be found that, while one subject will make a most successful slide, probably the next dozen others that you try will not give the effect at all, solely owing to their erroneous perspective and gradation. It forms an admirable test for true photography, though a somewhat discouraging one when you try it. It may be noted that the best effects are generally obtained when the inner margins of the prints are most closely trimmed so that the subject appears to stand out in front of the mount. An extra gin should be taken off the inner margins, and the mounting separation should be 3in. or over, while the results should be examined in the stereoscope at the greatest distance possible. Half-tone prints will often give a good effect, and we may cite as an example of a good subject Mr. Cruwys Richard's "Adeline," which often appears as an advertisement illustration. With a suitable full-face figure a curious effect can be produced by inclining the figures towards each other, but trimming the edges parallel. If properly done, the lower part of the figure appears behind the frame, and the head in front of it, the effect being that of a person leaning towards you out of a window-opening. Hand-painted subjects will give equally striking results, provided the drawing, modelling, and gradation is true to nature.

**BURNLEY Camera Club.**—A change of secretaryship is announced, Mr. A. E. Cooper, of 51, Carter Street, Burnley, succeeding Mr. A. Jackson.

**THE Queen of Norway** has honoured the managing directors of Speight (Ltd.), the child photographers of New Bond Street, W., by accepting from them for Prince Olaf a copy of their work, entitled "Baby's Album." The volume was specially bound in grey jarrah roan, similar to the copy recently supplied for the Queen of Italy. Colonel Knollys, in acknowledging the gift, expressed the great pleasure it gave Queen Maud in accepting the album.

## A VISIT TO A DRY PLATE MANUFACTORY.

As briefly intimated last week, about forty members of the Croydon Camera Club, at the kind invitation of Messrs. Wratten and Wainwright, paid a visit to their works on the 5th inst.; every step in the manufacture of a dry plate from start to finish being explained and shown in actual operation under ordinary working conditions, except that the plates, regardless of waste of emulsion, were coated, dried, etc., under the full glare of the electric light. Light refreshments, both liquid and solid, of a most varied nature, were then partaken of in Dr. Mees' laboratory, the guests of the evening being well looked after by a number of charming young ladies daintily attired.

### The Arrangement of a Plate Works.

In welcoming all, Mr. S. H. Wratten, on behalf of the firm, said:—

I believe that the visit here of my fellow members will represent the first occasion on which a photographic plate works has been open to inspection, other than to those intimately concerned in the works. This might appear to be due to a natural conservatism, or a fear of exposing secret processes; but although these reasons certainly hold, there is, perhaps, a still stronger one why a plate works should tardily open its doors, viz., that of cleanliness. It is not possible to manufacture plates except under very strict rules as regards cleanliness, and although we shall not have the pleasure of your being here for more than a short time, yet owing to the dust which will unavoidably enter with you, it will not be possible to resume work until a full day has been given up to cleaning. When considering the best means by which we could utilise the time at your disposal, we thought that it would facilitate matters if I were to premise your entry to the practical manufacture by giving you a short description of what you will see, so that when you enter a department whatever is on view will be largely understood. We shall first visit the glass department, where the glass received from France, Belgium, and Lancashire, is cleaned and substratumed ready for coating.

### Cleaning the Glass.

Although glass cleaning is apparently a very easy task, yet it can only be satisfactorily done under certain conditions. There are some persons who cannot even handle a piece of glass without so affecting it as to make it practically impossible for it to be cleaned afterwards. This is a remarkable feature about glass, and one which we believe, if better known, would go far to explain many of the troubles which occur outside a plate works, and in branches of manufacture not connected with photography. The cleansing agent we use is a mixture of borax, whiting, and water, with occasionally a small quantity of spirit.

You will notice that the glass is sent to the works very efficiently packed, and although it has very rough handling at the Docks, we seldom have to complain of breakage. It takes five persons to clean and pack our glass ready for coating. There are three sinks for cleaning, one to put on the detergent, and two to wash it off, after which the plate has to be substratumed. The substratum is simply a mixture of chrom-gelatin solution and water, which helps the film to greater adherence to the glass. After being substratumed, the glass has to be dried and inspected, and is then packed ready for coating.

### Coating, Drying, and Packing.

We shall next follow the glass to the coating department, and here you will see that we have two machines in running. The one we propose to coat with to-night was invented by Dr. Smith, of Zurich. Its chief feature is the Mariott-Bottle,

which controls the feeding of the emulsion. So effectual is this apparatus that we can coat with an error which seldom exceeds 2 per cent. Perhaps it is needless to add here that our staff have had long experience with the machine, and the uniform results obtained are largely contributed to by systematic note-taking and checking. You will understand that both in starting and running the machine the laws of surface tension and resistance must be taken into account. I may state, *en passant*, that a plate-maker's life is spent in infringing natural laws, and finding out the error of his ways.

The temperature of the emulsion at the time of coating is a matter of judgment. It varies in accordance with the season, and is governed by the length of the setting-band; this is 23 feet long, to prevent too early setting. After coating, the plates are stacked three inches apart on the slant, and removed to the drying room, where they remain for not less than twelve hours, afterwards being removed to the packing department to be examined, and if necessary cut to the required size, before the backing and packing. Regarding the "backing," it will interest you to know that a demand for backed plates has shown up to now an increase of 400 per cent. over the same period in 1905.

The most interesting feature of the packing department is the machinery employed for cutting, four machines being in constant use, and one being kept for reserve. By far the best of these instruments is the electrically-driven Munro machine. The original design for this, we believe, emanated from a plate-maker. The capacity of this machine is very large; but the rate we now work it is designed to avoid "rush," and although the speed may appear fast to you, it is in reality somewhat slow to a practised operator. It may also be interesting to you to know that two members of the Croydon Camera Club are responsible for the design of our cutting-machines. The illumination of this room for all colour plates as a safe-light "green," excepting only the "Allochroom" for which a suitable "red" is used. For all other plates, an orange red colour is employed, which gives an abundance of light without risk of fogging. We shall next pass on to the safe-light and colour-screen making department. While we are proud to be able to show you filters and safelights fulfilling the actual requirements of practice, we have also made recently a set of orthochromatic filters, which are noteworthy for their perfection, viewed either from the point of colour, or of optical accuracy, the glass being optically worked to the accuracy of one wave length by Messrs. A. Hilger, Ltd.

### Light Filters.

As you are aware, this branch of our business has only been in existence for a little over two years, but the progress we have made during this period has justified our enterprise. At present we have to make screens and mounts of many designs, but we hope that shortly some lens-maker will recognise that since lenses were first designed another branch of photography has come into existence, necessitating the use of light filters in addition to the ordinary lens glasses, and that the present lens mount is now deficient, inasmuch as it has no provision for holding a light filter in position. When the optician grasps this fact, we feel sure that the present lens mount will, by a very simple alteration in design, be so made that a variety of screens may be carried by photographers, any of which may be attached to the lens instantly, with an assurance that, being in effect part of the lens system, the screen will be automatically held in a correct position. I do not appeal to the optician to also make the colour filters. These must of necessity be made to suit the plates if the best results are to be obtained. Coloured

glass for screens has proved an abject failure, being often worse than useless.

### A Works Laboratory.

The following outline of the Work's Laboratory was given by Dr. C. E. Kenneth Mees:—

In welcoming you to the portion of the works which is essentially my department, you will understand that for us, this is in the nature of a house-warming. We are, indeed, in the occupied in moving in, and hope to be occupied in this for the rest of our lives. If you were to see apparatus around you in a complete and final state, this would represent not healthy vitality, but a stagnant finality and for this reason, while much of the apparatus here is complex and complete, much other apparatus is experimental, and necessarily incomplete. There are three important purposes in a works laboratory—

1. It is usually occupied with the purification and preparation of substances to be employed in manufacture.
2. It is necessarily occupied in testing and checking the various products of the works before issuing them.
3. It should be occupied in direct scientific research connected with the manufacture.

The first purpose has but little application here. The substances employed in the manufacture of photographic plates can be obtained of a very high degree of purity, and their preparation in the laboratory is unnecessary. In the preparation room you will see some dyes for experimental purposes being prepared for use. The testing apparatus of this laboratory is naturally elaborate. A good deal has been published concerning these instruments, and there is no need for me to recapitulate it here. The exposing machine, consisting of a standard light and a sector wheel, you see in this room. From this the plates go to the developing thermostat in the dark room, and from that to the measuring photometer, which you find in the office. The gradation photometer, which was exhibited in the Royal Photographic Society's Exhibition this year, has not been yet satisfactorily completed.

A useful testing instrument, is the small Tallent spectroscope, which has been improved in several ways, notably by the addition of a small wedge of neutral tinted glass at the slit, which gives a diversity of exposures at one time.

In the enlarging room you will find a new instrument for testing the optical flatness of filters, which takes, by means of a battery of lenses, a number of small photographs of a brightly

illuminated cross reflected from various parts of the filter; these photographs by their identity or diversity, showing whether the filter will be satisfactory or not. The purpose for which this laboratory essentially exists is that research may be done, and the main work here is the organising and carrying out of new research work.

### Works Research.

Laboratory research work usually falls into three divisions:—

1. The testing of new processes and products coming from other sources. Considerable attention, for instance, is devoted to getting information of any new dye or new printing process which may be introduced.
2. The working out of suitable testing apparatus. You see above your heads, for instance, a very long box which has been recently devised for the purpose of testing plates as to their suitability for astronomical work.
3. Work with a view to investigating and simplifying the actual manufacture and process.

Our dark room up here, for instance, is equipped with an emulsion thermostat, plate-coating machine, and drying cupboard, so that we can make and finish some two dozen whole plates of an experimental emulsion without in any way interfering with the manufacturing machines and arrangements.

We have, during the last year, worked out in this laboratory the "Wratten Panchromatic," and the new "Verichrome," and "Allochrome" plates. We have also made two sets of orthochromatic filters, the first published at the Croydon Camera Club, and the second, the Filter Yellow K filters, and also a set of tri-chromatic filters. We have in actual progress and sufficiently far advanced to be mentioned, work on optically perfect filters and dark room safelights, and on plates for special purposes, besides the experimental work, on colour plates, which is a matter of routine in this laboratory. In conclusion, I would call your attention to the following pieces of apparatus which have not before been published. A 6ft. diffraction grating spectroscope, which gives a spectrum 8in. in length in the visible portion of the spectrum; the large apparatus overhead for testing astronomical plates, apparatus for X-ray photography at the other end of the room, and the filter testing apparatus.

At the instance of the President, Mr. W. H. Smith, a most hearty vote of thanks was tendered Messrs. Wratten and Wainwright, for the unique evening spent, as interesting as it was instructive.

## A SYSTEM OF STUDIO RECORDS.

(From the "Photo-Beacon.")

At a recent meeting of the Suburban League of Professional Photographers the principal subject for discussion was the very important one of studio records, the methods of keeping tab on all orders and of filing and storing negatives. The average photographer has had little opportunity of seeing the systems followed by all alert business houses these days, but he may rest assured that in one and all of them experts have complete yet simple plans whereby the head of a department can keep in touch with every detail by studying a form report each morning.

In tackling this knotty problem, we started out to learn the system followed by the photographer at whose gallery we met. We analysed the whole procedure, from the moment a prospective customer enters the studio until the last print of the order is delivered and the negatives filed away. Then discussion was started on alternative methods. It was my business to play the part of a listener, to note down what was said, and to endeavour, if possible, to catch the best points suggested, then blend the good features into one inclusive system. I found that each man had devoted special attention to one feature of studio routine, and it was very interesting to listen to two men thrashing out the strong and weak points

of each other's methods. After three hours' solid discussion, it was agreed the following system ought to be about right for 95 per cent. of all the galleries in this country.

The first entry is ordinarily made when the customer makes a deposit—part payment, it was agreed, was a better term to use. The general opinion was that after the sitting was the best time for this phase of the transaction, unless the sitter voluntarily offered the money earlier. Most of those present made the first entry in an ordinary day-book, thus:—

JUNE 12, 1906.

Paid out		Price.	Paid.
dols.		dols.	dols.
	John Smith, 64, Main Street, 1 doz. cabs. ....	5.00	2.00
	Miss J. Jones, Altona, 6 cabs, duplicates. ....	2.00	2.00
	The Mercantile Co., 12 (8 by 10). Amount due ..		8.00
1.53	The Gas & Coke Co. ....		
	Miss M. Smith, 24 Walnut, 1 doz. half cabs. ....		
.25	Wrapping paper ....	4 00	
25.32	J. Anderson, Berlin, 6 (8 by 10) house ..		
	The Photo Supply Co., May account ..		
27.20	Totals for day ..	14 00	13.00

This shows the day's business, and by carrying the totals

to a separate page one can readily keep tab on the business for each month and the year.

One member preferred to write all orders on a duplicating register, such as is in use in many general stores using the following form:—

**C. W. LONGDON.  
PHOTOGRAPHER,  
70 STATE STREET.**

No. 80703 Chicago 4/14 1906  
M. F. L. Dundas Todd  
Address 808 Security Bldg.  
Style and Size 12 Style C. Platinum  
Price 1.00 Paid 5.00  
Due 5.00 Delivered \_\_\_\_\_

Please bring this Check when calling for Pictures.  
Always bring your Proofs.  
Extra charge for finishing from more than one negative.

The slip given the customer is his receipt, the duplicate is placed on a file, and from it all necessary entries are made in the register books, including the cash transactions.

In a small studio the photographer has no difficulty in telling the sitter's name when he examines his negatives the day after the exposure is made, but in a busy gallery, where there may be from a dozen to fifty sitters every day, some method of record must be adopted. In such a gallery the sitter usually presents to the operator a card on which is written the particulars of the sitting. It also has the serial number, which must be written on the negative. The usual practice is for the operator, after the exposure is made, to slip an edge of the card into the holder, and it is then the duty of the dark-room man to write this number on the edge of the plate before developing, so that it will be permanent. A hard, round-pointed lead pencil will do all right; failing that, the head of an ordinary match; in fact, anything with which a firm impression can be given without tearing the film. The number is best placed in the centre of one edge, as if on the corner it may be obliterated when handling the negatives. When several exposures are made on the same subject, all plates are marked with the same number. If orders are made from more than one negative, each is then distinguished by the addition of the letters A, B, C, etc.

We will suppose the negatives made and ready for the printer. Those that are considered to be worth proving should be placed in what is known as a "waiting order bag," which is simply a 7 by 9 envelope of strong paper, in which they will be protected from dirt and scratches and at the time be all kept together. On the flap of this envelope is written the number of the sitting, and if the packages are all set on end, with the flaps up, and all facing one way, it takes only a few seconds to find the set of negatives wanted. In this form they are sent to the printing room to be proved, then returned to the envelope.

Proofs being made, marked on back with number, delivered and returned, we now come to the most intricate part of the photographic business, and here is where I have pleasure in presenting a system which is decidedly original, and, I think, by far the simplest I have yet come across.

I am led to understand that it is the invention of a Chicago reception-room lady, who gradually evolved it out of the

fulness of her experience. I have watched its working in practice, comparing it with systems based on the card principle that are so useful in general lines, and I think it is far better than the latter, because in fact it is a card system with the addition of the proofs, thus providing in less than a minute all the information the photographer or the customer wants to know.

The photographer takes a sheet of thick manilla paper, 4 in. by 12 in., and doubles it in the middle so that it becomes a four-page folder, 4 in. by 6 in. On the first page of this folder he prints the following form:—

No. \_\_\_\_\_  
Name. \_\_\_\_\_  
Style. \_\_\_\_\_ No. Negs. \_\_\_\_\_  
No. Prints Ordered. \_\_\_\_\_  
Proofs Ret. \_\_\_\_\_ Prom. \_\_\_\_\_  
Remarks \_\_\_\_\_

Short \_\_\_\_\_

Duplicates \_\_\_\_\_

Short \_\_\_\_\_

It is much condensed here, to save space; the other pages are left blank. On the inside he pastes each proof from which an order is given by one edge, and on each proof is marked the number of the order, together with notes to retoucher and printer; in fact, he frequently outlines the limits of vignetting or trimming.

This folder goes first to the retoucher, being placed inside the "waiting bag," already referred to, which now contains only the negatives from which orders are to be finished, all others having been discarded. At the same time there is placed an envelope in the incomplete drawer, referred to in next paragraph, so as to keep track of the prints, as in even the best regulated studios a negative is apt to get sidetracked once in a while. From the retoucher the negatives go to the printer. After each toning the finished prints are sorted out, and those of each order are placed in a large envelope marked with the sitter's name—in fact, the same kind that is used for the "waiting bag"—and sent to the reception-room. Here they are arranged alphabetically in two separate drawers, one for unfinished orders, the other for finished. If a customer calls for an incomplete order the reception-room lady delivers the prints on hand, marking on the envelope the number delivered and date, then returns the envelope to the drawer. She thus can know in a few seconds exactly how each order stands. After next toning-day the printer carries the entire contents of the incomplete drawer to the finishing-room, places the prints in the envelopes, and checks his "short" notes with those on the envelopes. The incomplete orders are

returned in one pile, finished orders in another, the latter being accompanied by the order folder. For the reception of these folders he has small boxes, which hold 100, and each is filed away as the order is completed. It will be seen that each folder is now a part of a very perfect card system—because it can be found in a minute, and when found it has all the information the customer wants to know. The presence of the prints avoids the necessity of making a trip to the printing-room to get a set of negatives from which the customer may select one for a recorder. It need scarcely be added that duplicate orders go through the same routine.

If any balance is left unpaid when full order is delivered the amount is placed in an ordinary card system ledger. In a small business an ordinary notebook will be enough.

The system outlined above is really a combination of the best parts of those followed by three different men. It was pointed out that in a large business there could be added with advantage a print record book, so that stricter tab could be kept on the orders after they were sent to the printing-room, so as to prevent any negative being accidentally set aside and forgotten. In this book is entered the name of each

customer under the date on which the negatives go to the printing-room. After each toning and before the prints are placed in the envelopes already referred to, the proprietor gets the printer to call off the prints on hand for each order, and the number is entered opposite the sitter's name. By this part of the system any neglect is readily found out.

One reader informs me that he finds numbering by date to be the best method he has yet tried. For example, all sittings made on June 12, 1906, will bear the number 61206. His negatives are returned to the original plate box and the boxes are stacked on edges in the original cases. In case of a reorder he pulls out the box bearing the proper date, and at once shows the customer the negative.

In most studios the odd-sized plates are rather a trouble, as, if numbered with the series given the cabinets, they leave blanks in sets of the latter. It seems to me that the date system would work very well with such odd sizes.

I am prepared to furnish any or all of the essentials for this business system, particulars of which will be found in the advertising pages.

F. DUNDAS TODD.

## ON THE USE OF SULPHUROUS COMPOUNDS AS DEVELOPING AGENTS.

(A communication to the Société Française de Photographie.)

The basic developers now used in photography are generally in the form of salts, such as the hydrochlorate or sulphate, and rarely is the base itself used as in the case of paramidophenol.

The employment of the base itself has the advantage of obviating the formation of alkaline chlorides or sulphates when an alkali is used as one of the ingredients in the developer. The chlorides and sulphates thus formed in the solutions in considerable quantities diminish considerably the energy of the developer.

The reason why the bases are so rarely employed is because they oxidise so rapidly when exposed to the air. We have endeavoured to obviate this defect by forming stable compounds of these bases with sulphurous acid. This acid would combine with the alkali contained in the developing solution, and forms sodium sulphite, which, as is well known, is used in all developers.

We have been able to obtain compounds of sulphurous acid with the bases of paramidophenol, methyl-paramidophenol, and paraphenylene diamine.

These compounds were prepared either by the action of gaseous sulphurous acid on the free bases suspended in water at 177 deg. Fahr., or by crystallising from cold solutions of the bases in commercial 40 per cent. sodium bisulphite lye. In certain cases, that of methyl-paramidophenol for example, the compound may be prepared by heating at 177 deg. Fahr., a salt, the sulphate of methyl-paramidophenol with a solution of anhydrous sodium sulphite with about one-fourth of its volume of sodium bisulphite.

The principal properties of these compounds are as follows:—

### The Compound with Paramidophenol.

White crystals having a faint smell of sulphurous acid, which do not turn brown when exposed to the air as quickly as paramidophenol. Very slightly soluble in cold water, about 0.05 per cent. at 60 deg. Fahr., more soluble in hot. The crystals dissolve easily in a warm solution of sulphurous acid, and are deposited on cooling in small white scales, which fuse

at 365 deg. Fahr., the same as paramidophenol with abundant evolution of sulphurous acid.

The amount of sulphurous acid, as sulphurous acid, after oxidation with bromide was—

	Found	Calculated for
H <sub>2</sub> SO <sub>4</sub> %	8	(C <sub>6</sub> H <sub>4</sub> OHNH <sub>2</sub> ) <sub>2</sub> H <sub>2</sub> SO <sub>3</sub> 24

It is not then a sulphite of paramidophenol, but without doubt an addition compound which practically corresponds to the formula—

### The Compound with Methyl-Paramidophenol

Methyl-paramidophenol, the sulphate of which is known as metol, fixes sulphurous acid more readily than paramidophenol. The combination is stable and has no smell of sulphurous acid. It is more soluble in cold water, 3.5 per cent. at 60 deg. Fahr., and this enables it to be used direct as a developer in the presence of sodium sulphite, and without the use of an alkali.

It forms small white crystals, which do not alter in the air and which melt at the same temperature as methyl-paramidophenol, 190 deg. Fahr., giving off sulphurous acid. It can be easily crystallised in a saturated solution of sulphurous acid with about one-fourth of its volume of saturated solution of sodium sulphite. Examined as the former compound it would seem to be an addition compound having the formula approximately—

To test its stability in air, the quantity of sulphurous acid was estimated at intervals, it being kept in a half-filled bottle lightly corked. The following results were obtained.

	H <sub>2</sub> SO <sub>4</sub> Per Cent.
Initial strength ...	12.98
After two days ...	12.6
After six days ...	12.5
After six weeks ...	11.5
After three months ...	11.5

This proves that the compound is relatively stable and practically can be used without special precautions.

### The Compound with Paraphenylene.

We have also obtained this compound in the form of small white crystals, having a faint odour of sulphurous acid, very soluble in cold water, 19.5 per cent. at 60 deg. Fahr., which are stable in air, and melt at 279 deg. Fahr. (paraphenylene melts at 297 deg. Fahr.), and evolve sulphurous acid. The formula is approximately  $9(C_6H_4NH_2NH_2) + H_2SO_3$ .

These compounds have developing powers comparable to those of the free bases from which they are derived. The solubility of the methyl-paramidophenol compound enables it to be used as a developer with only the addition of sodium sulphite. They are all sufficiently stable that they can be practically kept without alteration, especially in the solid state, which is not the case with the free bases. The use of these compounds as photographic developers is patented.

## THE SWAN NEW PROCESS ET QUIBUSDAM ALIIS.

THE article which appeared in "The Times" of August 28 on the new process of Sir Joseph Swan and his son, Mr. Cameron Swan, has not received, I think, the attention it merits. As it makes also certain claims for the new process, I should like, in no hostile spirit however, to show that, ingenious and original as the method as described undoubtedly is, yet it has important limitations which will not bring about the revolution in the "printing, paper-making and book-binding industries" as stated in "The Times," for the very reason that the revolution, as regards printing at least, has been accomplished. Any one who remembers, as I can, the conditions of printing 30 or 40 years ago, both as to machinery and paper in relation to process work, will see a vast difference. In one thing only I think we have retrograded, viz., the introduction and extensive use of the so-called "art papers" very aptly termed by "The Times" writer "lath and plaster." The difficulty of printing even with the present wonderfully improved mechanism, fine half-tone blocks produced by the screen grain method, has rendered it necessary to resort to the heavily-loaded and calendered stuff misnamed "art paper." In this respect the Swan new process may effect an important reform and enable fine screen grain work to be printed on ordinary good paper.

The idea of the Swan process is certainly to some extent original, and the method of carrying it out as described in the patent is very ingenious; but it can hardly be expected as regards half-tone to equal and certainly not to surpass the technical beauty and effect of a good print from a good intaglio plate where that beauty and effect consist not only in the velvety surface produced by the pile of the ink pulled out of the hollows, but—especially where damp paper has been used—the slight emboss produced by the "fronting" and blankets of the copper-plate press. And here I may remark on the curious fact that the antipathy for water evinced by printing ink—antipathy constituting one of the important factors in lithographic printing—is altogether absent when wetted paper is used either for plate or typographic printing. Printing ink takes most kindly to damp paper, and when the paper dries there results that delightful surface so pleasing and restful to the eye which the present horrible and heavy "lath and plaster" compound so woefully lacks. There is also to be noted the solidity of impression given by damp paper; an absence of mealiness. Fine examples of this may be seen in some of the early productions of the printing press. The wetting trough and board were for a long period and within living memory an essential part of a letter-press printer's plant. I am inclined to think it might be restored with some advantage to the legibility of book-work and quality of surface of the paper. But oh! what would be the appearance of half-tone illustrations produced by the screen grain? Something horrible to see! Here the Swan process would have, I think, an advantage very marked if damp paper could be used.

To return now to that process of printing from intaglio plates after the lithographic manner, it cannot, as I have said, equal the result obtained by the copper-plate press, not only for the reason given, but where "wiping" is done by the skilled hand of the artist workman—i.e., one not merely an artisan working mechanically, but with appreciative brain and instinct guiding his deft hand, the result is unapproachable by any method at present known. It is the acme of the printing art. In lithographic printing the ink is squeezed flat on the paper with a tendency in heavy inking and pressure to "spue" in the solids and thicken-lines. In this respect I consider the Swan process would show to great advantage, as the sunk parts of the plate will not get as heavy a squeeze as the level parts, and the

paper will pick up the ink from the hollows more approaching plate printing—"sed longo intervallo"—than in litho printing. Whether the solids will be "mealy" will depend, I should think, on the depth of the intaglio in those parts. If very deep the paper would probably not pick up the whole of the ink. I have not yet seen any examples of the work. I have no doubt it is good, as I feel sure neither "The Times," nor Sir Joseph Swan—an honoured veteran in photographic invention—nor his son, Mr. Cameron Swan, would put forward so prominently anything which is at all crude or unreliable. I take it for granted, therefore, that the new process is good and thoroughly practicable, its two special features being pure whites and rich blacks with gradations between those extremes. The process I have said is original in its conception, but this is to be modified to some extent by the fact that printing from an actual intaglio on stone producing exceedingly fine and delicate work has been long known. A ground of lamp black mixed with gum water is put on a litho stone, and when dry the subject is scratched in with a diamond point, and shows white against black. The works are then filled in with greasy material and the ground washed off. Printing is then done in the usual way, the ink taking to the greasy hollows and being rejected by the wet parts. Of course, the Swan process materially differs in the subject being automatically produced on metal and in half-tone screen grain as well as in lines.

As regards pure whites and rich blacks with gradation between those extremes, can these not be obtained also from suitable transfers taken from good intaglio plates and put down on stone, zinc or aluminium, either for the flat or rotary litho press? With the exception of any special advantage for effect due to diminished squeeze on the extreme and medium depths it undoubtedly can, and with this further advantage of very cheap duplication for long numbers by putting down several transfers. I have, myself, no craze for large quantities, and have had all my business life a preference for the little and good—"the few and fit." I prefer good results from hand-press work, either copper-plate, litho, or type-press, to any amount of millions reeled off by machine à la "Daily Mirror," or lesser quantities and better quality, as "The Sphere," etc., etc., results showing little of the human element. So no doubt I should prefer a good Swan print direct from the original plate to one produced from a transfer however good, reeled off from a machine however perfect. But from the commercial point of view the Swan plate, printing only one at a time, would have no chance against multiplication by transfers. Then if it comes to the question of the best means of obtaining a half-tone intaglio plate which can give good, practical transfers, I say without fear, justified by experience, that my Dallastint natural grain will be more suitable than any product of the screen grain. A very material point in favour of the Dallastint natural grain is that it can be made so fine as to carry microscopical detail, and will bear an immense enlargement without showing disagreeable texture. I have recently had and shown to the editor of this journal a bromide enlargement made from a print from an Intaglio plate 1 produced in 1869. The size of the original print is 4in. x 3in. The enlargement is 20in. x 16in.—i.e., more than 26 times the area of the original. The texture of the enlargement is anything but coarse. It can be described truthfully and without the least exaggeration as "fine." I am satisfied the grain of this subject, as well as that of the portrait of Adam Solomon, which I engraved in 1867 for the BRITISH JOURNAL ALMANAC of 1868, where it forms the frontispiece, could be enlarged to quad demy size, poster, or even larger, without

showing unpleasant texture or creating difficulties in printing. The same may be said also of the "Kenilworth Banqueting Hall," which I engraved in 1863, and, accompanied by a paper I wrote, was brought in that year before the British Association at the meeting at Nottingham. I printed some thousands from the plate (which I still possess), and the prints formed the frontispiece to the 1868 volume of the "Photographic News," the editor of which, the late G. Wharton Simpson, pronounced it the greatest advance which had been made in photo-engraving. Copies of the volume can be seen at the British Museum, the Patent Office Library, and the Library of the Royal

Photographic Society. I hope I am not blowing my own trumpet unduly when I say that example of my process shows qualities of a high order which the present method of photogravure does not possess and cannot possess without expensive handwork.

Now what would be the appearance of the screen grain in such an enlargement as I have described? Examples were to be seen on many hoardings advertising "Mellin's Food." They were hideously coarse and exaggerated unless seen from a very long distance. The Swan process, being a screen grain method, would not be suited for enlargement.

DUNCAN C. DALLAS.

## A NEW METHOD OF MEASURING THE TIMES AND EFFICIENCIES OF PHOTOGRAPHIC SHUTTERS.

(Continued.)

The cam is of such a shape that when the shaft has turned to a certain position, the arm F G drops over the abrupt angle of the cam, owing to the tension of the spring attached to A. This causes the bar C D to move upwards, sufficiently nearly in a straight line in a direction along its whole length.

The bar C D has a long slot cut in it, and a bolt passing through this at M clamps the bar L M in any convenient position. It will be seen that the point L of the bar L M has adjustments in any desired directions in the plane B C D E, by compounding a motion of M along the slot, and a twist of the whole bar L M about M. A screw passes through the bar L M at L in a direction normal to the plane B C D E, and gives an adjustment in this direction. By these adjustments the end of this screw is brought into gear with the shutter release, and the upward motion of the rod C D then serves to release the shutter. This motion can be regulated to suit the particular shutter under test.

With the mechanism so far described the release of the shutter would take place at each revolution of the shaft. This was found to be very inconvenient when high speeds of shutter were being dealt with, as there was not sufficient time, after setting the shutter, to get ready to observe the image. To evade this, a little catch, P Q (Figs. 5 and 6) was made to hold back the bar F G, except when release was wanted. P Q is pivoted at O, and the end P is placed opposite the core of an electromagnet R. A little spring keeps it up against the bar F G, except when the electromagnet is in action, that is, when the key switch S is down.

The electromagnet is put at such a distance that it exerts a force sufficient to overcome the little spring alone, but not this spring and the friction force between Q and F G. Thus it is only when the cam has lifted F G clear of Q that the catch Q is drawn aside by the electromagnet. This takes place when the portion opposite to the sharp angle of the cam K is in contact with F G, so that the arm F G is free to follow the cam when the angle turns round to G.

By the means just described the shutter may be set, and the release can be made by pressing down the switch S, as soon as the observer is ready to make a setting for the end of the visible image.

Several ways have been thought of, and tried, for holding the shutter in position. It seems best to actually fasten the shutter down by screws to a wooden support with an aperture in it. This support is attached to the lens holder, and the shutter is brought as close as possible to the lens.

It has been found convenient in practice to work with two images. A second source may be arranged for by putting up a second lamp, or two reflected images of one lamp may be used. This double source, however formed, is made such that the images formed by the lens are about one inch apart. Each image is observed from behind the rotating disc. One is formed on a strip of ground glass, and the other is used for "end" settings."

Fig. 7 shows the arrangement. The lines A B, A' B' represent the two images. A' B' is received on the strip of ground glass G G. Part of the image A B is observed on a small piece of ground glass, fixed at the end of a short tube, shown in Fig. 7 as a circle C. The tube is mounted in a slide E, which moves up and down the bar H K. The ground glass on C has a line marked on it pointing to S, and the slide D E fixed to C, ensures this line passing through S. On

E is fixed a pointer P, and the angular position of the line on C is read by means of P on a properly graduated scale. The graduations give the position in decimals of a complete revolution.

Thus if the bar is set so that the line in C corresponds successively with the two ends of the visible image, the difference of the two readings gives the decimal of 360 deg. subtended at S by the visible image—i.e., it gives the fraction  $\theta/360$ , which came in the original formula,  $t = \theta/360n$ . It only remains to divide this by  $n$ , the number of revolutions per second of the disc, to find  $t$ , the time of shutter exposure.

In considering the quantity  $\theta/360$ , it is clear that  $\theta$  cannot be measured in the way described if it exceed  $360^\circ/m$ , where  $m$  is the number of slots in the disc. On the other hand, greater percentage accuracy of setting can be made, when  $\theta$  is as large as convenient. It is best to arrange the speed of the disc so that  $\theta$  is about two-thirds of the angle between consecutive slots of the disc.

The use of the second image A' B' is to enable the observer at once to form an idea as to whether the speed of rotation is suitable to the time of the shutter. He can also see about where the ends of the image are. The shutters dealt with were often widely different in actual performance from nominal performance, and the time engraved on the shutter did not give much idea as to what was a suitable speed for rotating the disc.

Fig. 7.

Remembering that times of exposure to be measured vary between wide limits (say two seconds to one-fourth-hundredth of a second), it will be seen that it is very necessary to have a ready means of altering greatly the speed of the disc. At first this was attempted by driving the disc by an electric motor and altering the volts on the

motor by means of a variable resistance. In this way the speed could be varied considerably, but not nearly enough. To meet the case it was necessary to have a pair of coned pulleys, giving speed ratios of 10 to 1 and 1 to 10 at the two ends. They were not connected by the ordinary crossed belt, but by a method devised by the author.

A rubber ball, merely resting between the two cones, transmits the motion from one to the other. The ball can rapidly be moved from end to end of the cones, giving the desired speed change. With this arrangement the cones can be used down to extremely small radii, where it would be impossible to have a belt drive. Fig. 8 shows the appearance of the system.

Fig. 8.

This, then, completes the apparatus. The general appearance is shown in Fig. 9. It will be well to consider to what inaccuracy the method is liable. The distance between consecutive slots, where the image A B is formed, is about 5 cm., and observations are made on a length of 3.5 cm. It is quite easy to make a setting within 1 mm. at either end, so that we have an error of .2 cm. in 10/3 cm., i.e., a 6 per cent. error. The finite width of the slots of the disc perhaps introduce a similar amount. In taking the speed of rotation an error of several per cent. may be expected, and variation of speed of the motor introduces still further error. On the whole, the author is confident that there can in no case be an error of more than 20 per cent. of the quantity measured. A great many readings have been taken, and repetitions quite justify this as an outside estimate of possible error.

In a few cases a shutter has on different occasions given results differing by more than 20 per cent., but this has only occurred when the shutter has been acting in a variable manner. Of course, it cannot be expected that a shutter should have precisely the same performance from day to day, and after further wear.

As indicated in the title, tests for efficiency have been made with a number of shutters. What has actually been measured is the length of time during which the shutter is open beyond a certain amount. In the cases of shutters which open from the centre, the method followed was to put up a stop as near the shutter as may be, and shaped like the aperture of the shutter. The shutter had then to open beyond this aperture before any image was formed. The ratio of the area of this aperture to the aperture when the shutter was full open, gave the amount of lens uncovered, when the stop was removed.

Stops were made to eclipse about  $\frac{1}{4}$ ,  $\frac{1}{2}$ , and  $\frac{3}{4}$  of the aperture, and in each case these stops were of the shape of the shutter when open to an equal extent. After readings have been taken and reduced, with the various stops in the way, it is possible to draw an efficiency curve in which abscissas give time during which the shutter is open, and ordinates give the aperture beyond which the shutter was open for this time. The efficiency is given by the ratio of the mean abscissa to the greatest abscissa.

Measurements were made on a number of shutters to test the

accuracy of the method. Several of these were old, and the experiments must not be looked upon in any way as tests of the type of shutter, as no special care was taken to secure representative shutters. The object of the investigation was to test the method of measurement and the possibility of applying it to shutters of various forms.

Results are given which were obtained from four shutters. Of these the first two were diaphragm shutters, and the others roller blind and focal plane shutters, respectively.

In the case of shutter No. 1, the actual readings taken are reproduced so as to illustrate the method in which results are arrived at. These are given in Table I. Column I. gives the nominal times of the shutter; column II. gives the reading for one end of image, minus the reading for the other end—i.e., the angle subtended at the centre of the disc by the visible portion of the image, in decimals of a complete revolution; column III. gives a number of revolutions of the disc per second, usually measured over ten seconds; column IV. gives actual time of shutter, being  $II. \div III.$

Two independent sets of readings, A and B, were taken for comparison.

Nominal Times.	Readings.	Revs. per Sec.	Actual Time.
<b>A</b>			
$\frac{1}{10}$ .....	.142-.067 .....	.12 .....	.63
$\frac{1}{15}$ .....	.162-.066 .....	.19 .....	.45
$\frac{1}{20}$ .....	.145-.067 .....	.21 .....	.37
$\frac{1}{25}$ .....	.160-.068 .....	.34 .....	.27
$\frac{1}{30}$ .....	.132-.012 .....	2.0 .....	.020
$\frac{1}{40}$ .....	.172-.116 .....	3.6 .....	.0156
<b>B</b>			
$\frac{1}{10}$ .....	.124-.065 .....	.09 .....	.64
$\frac{1}{15}$ .....	.138-.066 .....	.17 .....	.42
$\frac{1}{20}$ .....	.142-.067 .....	.22 .....	.35
$\frac{1}{25}$ .....	.142-.068 .....	.35 .....	.21
$\frac{1}{30}$ .....	.114-.110 .....	3.0 .....	.0180
$\frac{1}{40}$ .....	.173-.113 .....	3.4 .....	.0173

Here there seems to be good agreement of results. The worst difference is in the case of the  $\frac{1}{25}$  additional nominal, where it is 25 per cent. of the mean value of the two results. This is, no doubt, partly due to the performance of the shutter not being quite constant. But the amount by which some of the times differ from the nominal times is far greater than the amount which might be attributed to inaccuracy of reading. Thus the nominal  $\frac{1}{50}$  is nearly correct, while the nominal  $\frac{1}{25}$  is really about  $\frac{1}{4}$ .

When arrangements were being made for testing efficiency one of the leaves of this shutter was broken. This was afterwards replaced by a new leaf, after which the following results were found for the two fastest times. Three stops were made of proper shape, and these were placed close to the iris diaphragm. The three stops eclipsed  $\frac{1}{4}$ ,  $\frac{1}{2}$ , and  $\frac{3}{4}$  of the aperture respectively. The results are in—

Nom. Time	Stop 3.	Stop 2.	Stop 1.	No Stop.
$\frac{1}{10}$ .....	.093 .....	.014 .....	.018 .....	.022
$\frac{1}{15}$ .....	.0102 .....	.014 .....	.017 .....	.021

The corresponding efficiency curves are shown in Figs. 10a, 10b, the efficiencies working out to be .64 at  $\frac{1}{50}$ th second, and .66 at  $\frac{1}{100}$ th second.

Fig. 9.

Shutter No. 2.

The following Table III. shows the results found for shutter

No. 2. Stops 1, 2, 3, were made of the proper shapes. Their areas were measured by planimeter, and were found to be .7, .47, .26 of full aperture, respectively. After one complete set of results (A) had been found, a second set (B) were taken for comparison, and two more sets (C and D) for full aperture taken at an entirely different time are shown for comparison with (A) and (B).

The A result for 1/10 with stop .47 is obviously due to either a misreading or a failure in the action of the shutter. The headings .7, .47, .26, 0 of the columns indicate the amount of aperture exposed for a period of time indicated in the table.

TABLE III.  
Shutter No. 2.

Amount of Apert. Exposed by Stop.	.70		.47		.26		0		
	A	B	A	B	A	B	A	C	D
1/10	.0026	.0026	.0039	.0025	.0041	.0045	.0054	.0038	.0046
1/20	.0030	.0032	.0041	.0043	.0043	.0048	.0053	.0037	.0054
1/30	.0040	.0029	.0041	.0050	.0061	.0050	.0067	.0066	.0056
1/40	.0150	.0040	.0043	.0048	.0072	.0065	.0081	.0078	.0073
1/50	.0100	.0103	.0235	.0103	.0118	.0114	.0195	.018	.020
1/60	.050	.037	.071	.042	.034	.039	.064	—	.06
1/80	.11	.09	.168	.102	.111	.140	.157	.13	.15
1	.21	.26	.224	.386	.247	.268	.296	—	—

TABLE IV.  
Means of Table III.

Aperture Exposed.	.70	.47	.26	0
1/10	.0026	.0037	.0043	.0046
1/20	.0031	.0042	.0048	.0056
1/30	.0035	.0046	.0056	.0063
1/40	.0045	.0046	.0069	.0077
1/50	.0102	.0103	.0130	.0192
1/60	.044	.067	.041	.062
1/80	.10	.135	.133	.146
1	.24	.28	.26	.30

In these results it will be noticed that from one second nominal to 1/100th nominal, the nominal times are longer than the actual times. Thus:—

1 sec. nominal is really $\frac{1}{10}$
$\frac{1}{10}$ " " " " " "
$\frac{1}{20}$ " " " " " "
$\frac{1}{30}$ " " " " " "
$\frac{1}{40}$ " " " " " "
$\frac{1}{50}$ " " " " " "
$\frac{1}{60}$ " " " " " "
$\frac{1}{80}$ " " " " " "
$\frac{1}{100}$ " " " " " "
less than $\frac{1}{100}$

The 1/25 nominal is only 1.7 times as long as the 1/300 nominal. The performance of the shutter when set at speeds of  $\frac{1}{4}$ ,  $\frac{1}{2}$ , 1 sec. nominal does not seem to remain constant, and so the results worked out with a view to finding efficiencies at these speeds are contradictory.

The efficiency results for the faster speeds down to 1/10th nominal work out at 1/300, 68; at 1/200, 65; at 1/100, 64; at 1/25, 61; at 1/10, 55; showing a steady decrease of efficiency.

#### Roller Blind Shutter (No. 3).

In this shutter the lens aperture is exposed by a wide gap in the blind. Suppose  $d$  is the width of this gap and  $a$  the diameter of the aperture to be exposed, then the complete time of exposure is the time in which the blind moves a distance  $d + a$ . It is clear, then, that this time depends partly on the size of the lens aperture.

With this shutter two sets (I. II.) of readings were taken with the shutter working across an aperture of  $1\frac{1}{8}$  inches. Results are shown in Table V.

TABLE V.			
Nom. Times.	I.	II.	Mean.
1/10	.066	.050	.063
1/20	.045	.046	.047
1/30	.037	.042	.040
1/40	.0325	.036	.034
1/50	.031	.032	.032

It will be seen that the agreement in the two sets of readings is fairly close.

In this shutter no correct statement of the time of exposure given can be made without at the same time the size of the lens aperture with which it is to be used. As before, if  $d$  is the width of the gap and  $a$  the diameter of the lens aperture, the shutter has to move through a distance  $d + a$ , while the lens is partially or wholly uncovered. It is clear that if  $a$  is altered the time of exposure is also altered. The most natural statement seems to be the time of the shutter in exposing a point. As  $d$  is large compared with  $a$ , we can assume some mean velocity  $v$  of the shutter without making much

error. Then the time  $t$  with aperture of diameter  $a$  is given in terms of  $T$ , the time over a point by relation

$$t = \frac{d+a}{d} T.$$

#### Focal Plane Shutter (No. 4).

In testing this, the shutter was placed close to the lens, and the time of exposure given by the shutter with slit of width  $d$  when passing over an aperture of width  $a$  was found. This is the same thing as the time for slit of width  $d + a$  to pass over a point, if we assume uniform velocity over this small width. From this was inferred the time taken by a slit of width 1 cm. to pass a point.

Six sets of readings were taken: two (A, B) for a point near edge of the plate which would first be exposed; two (C, D), for a point near centre of the plate; and two (E, F) for a point near the edge of the plate, which would last be exposed. From the results it is possible to notice the changing speed of the shutter as it crosses the plate.

The results are in Table VI.

TABLE VI.

Setting.	A	B	C	D	E	F
1.	.0132	.0126	.0113	.0107	.0084	.0088
2.	.0130	.0105	.0084	.0078	.0061	.0075
3.	.0035	.0037	.0019	.0019	.0053	.0061
4.	.0082	.0084	.0056	.0066	.0049	.0051
5.	.0078	.0077	.0047	.0062	.0045	.0044

Column I. gives the setting of the shutter which was used, and the remaining columns give corresponding times. Pairs of readings A, B, C, D, E, F, were taken for comparison, to see that the differences found for different positions was larger than that due to inaccuracy of reading. Comparing A with B, C with D, E with F, we see that in general the agreement is fairly close, and that the difference between the various pairs is a real one. This is put in a more convenient form in Table VII., where means of A and B, C and D, E and F, are given; also, the nominal times of the shutter.

TABLE VII.

Setting.	I. Edge First Exposed.	II. Middle.	III. Edge Last Exposed.	Nominal Times.
1.	.0129	.0110	.0086	$\frac{1}{10}$
2.	.0113	.0071	.0068	$\frac{1}{20}$
3.	.0031	.0064	.0057	$\frac{1}{30}$
4.	.0083	.0061	.0050	$\frac{1}{40}$
5.	.0078	.0050	.0045	$\frac{1}{50}$

It is clear that in position I. the shutter has not attained its full speed at any of the settings; and with the spring at its weakest setting No. 1, the full speed is not reached even by position II. This is also the case to a less extent with the other settings, but it is not supposed that the figures given have sufficient accuracy to distinguish certainly between .0050 and .0045, though the uniform run of the figures rather supports this view.

Fig. 10A.

Fig. 10B.

Between Columns I. and II. the difference is quite beyond the difference possible through error of reading, etc.

Some visual methods have been used for shutter tests, in which a lens has been employed to form an image of the various subjects observed. In two of these the shutter to be tested has been held close up to the eye. A little consideration will show that this cannot give a correct result except in certain cases. If the shutter is one which opens from the centre and then closes towards the centre, the

method may be correctly employed if the eye is placed so that it can see the object to be observed as soon as the shutter is very slightly open.

But a roller blind shutter is not correctly dealt with in this way. For, if the eye is placed at the centre of the aperture, it is only when the shutter has uncovered half the aperture that the eye can see the object to be observed; and after the shutter, when closing, has covered half of the aperture, nothing can be seen.

In other words, the time which could be measured by this means would be the time for which a single point (placed where the eye is) receives light through the shutter. On the assumption of any law of velocity of the shutter blind it would be possible to deduce the time over a lens of given aperture.

In other papers on shutter testing results have been published which show that the shutters considered differ very widely in nominal and actual performance. And the same feature is very noticeable in the shutters with which the author has had to deal. In the following table (VIII.) the results of a large number of his tests on different shutters are collected. The entries made represent the ratio of actual time to nominal time. Each horizontal row refers

to one shutter. The headings of the columns give a small range of time in which the nominal time of the shutter is included. In the case of two of the shutters which have a certain nominal time in common, one shutter gives an exposure of forty-three times the length of exposure given by the other. But the table explains itself.

TABLE VIII.—SHOWING RATIO OF ACTUAL TIMES TO NOMINAL TIMES.

Nominal by diminished or increased water supply, and by a brake fitted to the motor.

The construction of the actual rocker is shown in Figs. 1 to 3.

The two pillars, C and D, are fastened to the base A, Fig. 1, by screws. C is provided at the top with a hinge H, which is also fastened to the actual rocking board B. D prevents B from tipping over. The see-saw movement is produced by the eccentric E and conveyed to B by the roller R. The hinge is always beyond the middle of B, so that the roller always rests on the eccentric. The lift is about one-third of an inch at the end of B. The eccentric is fastened to a rod W, at the other end of which is the pulley wheel Z, which carries the driving belt.

Fig. 2 is the section through the rocker at right angles to Fig. 1. The whole arrangement is shown in Fig. 3.

The turbine stands in an ordinary developing dish, fitted with a waste pipe. At one end of the turbine axle is fitted a fan, so that the arrangement can be used for drying plates, papers, etc. When the revolutions are high the action of this is considerable. The fan is provided with a guard.

The transmission of the power to the plate rocker is obvious from the sketch. An ordinary rubber band is used which has the advantage of being easily changed, and working easily and noiselessly. Whoever has used this arrangement will never be without it.

It is a pity that something of the same kind cannot be obtained commercially, for everyone cannot make such an apparatus for himself.

Fritz Goos.

#### ADVERTISE.

In the "Association Annual," a publication issued by the Photographers' Association of America, Mr. Pirie MacDonald writes in the following characteristic vein:—

If it were possible to lay down a rule by which photographers could advertise, it would stultify itself, it would be foolish for everyone to pursue the same course, and any effect we might produce would be nullified by the work of the next man. Because "What is one man's meat is another man's poison" we are forced to devise methods which suit the particular case. However, there are three points which will bear discussion:—

Advertise what?

Photographs, of course; but just how? This is where the method must be found for the particular case. Photographs as such, photographs as a luxury, photographs as a necessity, photographs as art or photographs as utilitarian, because they are not doing their duty to their families if they are not properly photographed, or because they should use photographs in their business: prices, quality, or the personality of the artist: just which of these or the nine hundred and ninety other phases is best fitted to the particular case you will have to determine yourself, but: that your community is susceptible to advertising, you need never question.

Advertise where?

Whether to advertise to the subject, and try to interest him direct, or whether to advertise to his friends and breed a want for his photographs, whether to try to reach either of the classes direct by card, circular, booklet, or a demonstrator, or through general advertising mediums are all problems that the particular man and his environment must govern.

Advertise when?

When business is bad? When business is good? When we are short of money? When we have plenty of money? In spring, summer, autumn, or winter?

The answer is, "advertise all the time."

A farmer who takes crop after crop from his land and gives nothing back is called a fool: businesses are prone to go to seed because we are taking every penny out and putting nothing back. We should spend 10 per cent. of our gross receipts in advertising and then apply ourselves to it, as to any business proposition, and find a way of wisely spending it all.

So "advertise all the time."

THE Cowes Camera Club will hold its first exhibition on January 23 and 24 in the Victoria Hall, Cowes. Mr. S. J. Kimber will be the judge.

#### MR. J. T. SANDELL.—AN APPEAL.

The following contributions have been received in continued response to the appeal of Messrs. Thos. K. Grant and J. B. B. Wellington:—

## Photo-Mechanical Notes.

### Polishing Half-tone Screens.

A suggestion of Gustav R. Meyer, in the "Inland Printer," is as follows:—"Purchase 10 cents. worth of optical rouge at a jeweller's supply house. Put it into a bottle with about four ounces of alcohol. Take several pieces of cotton the size of your hand, shake up the rouge solution and apply a liberal quantity of it to each piece of cotton, let them dry, and the polishing pads are ready for use. Keep them in a box when not in use, to avoid grit and dust. These pads will do service a year. If silver nitrate should get on the screen, remove it with a piece of blotting-paper. Moisten the blotter if the silver has crystallised, and re-polish with pad."

### Half-tones on Metal Rollers.

According to the published specification (No. 11,071, 1906), the following process has been patented by J. W. Ippers, 101, Beekman Street, New York, U.S.A.:—"Making a half-tone photograph of a graduated picture or design, through a half-tone screen; making a gelatine plate on an elastic base; exposing the gelatine plate to light, through the half-tone photograph; developing the exposed gelatine plate, by bathing it in water, and thereby swelling into relief those areas of the plate which were under the dark areas of the half-tone photograph, while leaving in depression those areas of the plate which were under the translucent areas of the half-tone photograph, during the exposure; drying the developed gelatine plate in air; applying glycerine solution to the relief areas of the gelatine plate; applying ink to the depressed areas of the gelatine plate; transferring ink from the depressed areas of the inked gelatine plate to the periphery of a metal roller, by pressing the periphery directly and powerfully upon the gelatine plate; and etching away the uninked areas of the periphery."

Reference is made in the specification to previous Letters Patent. Nos. 266 of 1881, 15,022 of 1894 24,303 of 1895, 16,944 of 1899, and 8,457 of 1901.

The following photo-mechanical patent was applied for December 13:—

HALF-TONE BLOCKS.—No. 27,529. Improved manufacture of half-tone printing blocks. William Bell and Harry Bryce Bell, 19, Holborn Viaduct, London.

THE Proposed Camera Club in the West End.—The committee who have had this matter in hand since May last are now able to report that it is proposed to open the club early in January, provided about 100 town members join promptly. The premises are situate at 14 and 15, Conduit Street, Regent Street, and are already fitted for the purposes of a camera club; the accommodation occupies the whole of one floor, approached by a lift, and comprises lounge hall, club room, dark rooms, enlarging room, fitted with an enlarger with 11in. condenser, daylight work room, studio (32ft. by 12ft.), supplied with a 15in. by 12in. studio camera, with Goerz and Dallmeyer lenses, and open air printing accommodation. Should it be necessary at any future time, there will be room to extend the club premises. Those wishing to join without entrance fee, or desiring further particulars, are requested to apply at once to Mr. Henry W. Fairholme, Blenheim Mansions, Queen Anne's Gate, S.W.; or to Dr. A. R. F. Evershed, 19, Harley Street, W.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents were made between December 3 to 8:—

**DAYLIGHT DEVELOPMENT.**—No. 27,484. Improved daylight development apparatus for photographic plates. Carl Friedrich Aurich, 6, Bream's Buildings, Chancery Lane, London.

**DISHES.**—No. 27,944. Improvements in photographic developing dishes. Victor James Atterton, 173, Fleet Street, London.

**PRINTING FRAMES.**—No. 27,998. Improvements in photographic printing frames. Lionel Thomas Joy Haweis, 37, Chancery Lane, London.

**ENLARGING FRAME.**—No. 28,000. Improved photographic stand and equipment for use in bromide printing, for enlarging, reducing, and copying photographs, and for lighting and modelling flowers, fruit, and other small still life studies. Arthur James Lambert and Charles Henry Land, 8, Quality Court, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**WASHING TANK FOR PLATES.**—No. 10,153. 1906. The invention consists essentially of a box divided into two compartments—viz., a compartment for the liquid and one to hold a number of plates—by a partition so arranged that an opening extends along the bottom of it, and forms a communication between the two compartments, whereby liquid received in the one compartment flows, before passing out of the vessel, under the partition into and upward in the second compartment, thoroughly and uniformly washing the plates retained therein in a position parallel to the direction of the flow of the liquid.

In the figure water is admitted at 13, flows under the partition, and escapes by the wide aperture 15, which is at a lower level than the inlet 13. H. C. Hide, for Martin R. Jacobus, Ridgefield, New Jersey, U.S.A.

**FOCUSsing FINDER-CAMERA.**—No. 28,575. 1905. The invention consists of an additional detachable camera, consisting of a sliding body in the form of boxes, telescoping tubes, or the like, to fit loosely one inside the other. To the front end of one of the sliding parts is fitted a recess to receive the front lens board.

To the rear end of the outer box is fitted a recess to receive

a base, which consists of two rods, working inside two lengths of small metallic tubing, and at the rear end is also a focussing glass or screen.

The inside rods are fixed to a suitable piece of brass in the centre. Parallel with the edge is provided an elongated slot which permits a bolt to travel along to any desired point, when fixed by a brass strap to the front of the camera.

The two lengths of small tubing are fixed at their outer ends to a right-angled piece of brass, which is provided with a number of holes or slots to fit fixing screws, provided at the rear of the camera.

The claim is: "A detachable focussing device for photographic cameras, comprising a telescopic body, with a suitable lens and ground glass screen, so arranged that the image in the said instrument is focussed simultaneously with the image of the object to be photographed in the camera." James Preston Cribb, 127, Chichester Road, North End, Portsmouth.

**DARK SLIDE CARRIER.**—No. 24,813. 1905. This invention is a framework of either wood or metal, A, Fig. 1, made to fit into the interior (back) of the camera (but loosely, so as to permit of its free oscillation) and a baseboard F, upon which it should

Fig. 1.

Fig. 2.

rest. The frame-work is fitted with strips of wood or metal on its inner sides to "carry" the dark-slide in a horizontal position, and is so furnished with ledges that no light can get at the plate if the shutter of the dark-slide is withdrawn before the dark-slide is raised into position for exposure.

The other section at right angles carries the screen B, Fig. 2, of ground glass.

The entire framework thus formed is hinged at H at the bottom

Fig. 3.

edge, to the back of the camera, Fig. 3, in such a manner that when the plate-holder D is inserted (in the horizontal position) the screen is vertical, and in correct position for the examination of the image projected upon it, as shown in Fig. 3.

The operation of the apparatus begins when the plate-holder and the focussing screen are in these respective positions. The screen in its vertical position, having been used to locate and focus the image, may now be pulled forward and downward, thus bringing the plate-holder up from the horizontal into the position previously occupied by the focussing screen, and ready for "exposure," as shown in Fig. 4.

To secure the plate from being "light-struck" in its passage to this last-named position, if the shutter of the dark-slide be withdrawn whilst in the horizontal position, a covering of leather or other suitable material impervious to light is drawn and fixed over the opening thus momentarily caused, and, in addition, a

light tight framed cover, G, which is used for the purpose of a "focussing cloth," is brought down over the focussing screen, thus securing for the sensitive plate (now in position for exposure) immunity from stray rays of light. But if the shutter be not

Fig. 4.

withdrawn until it is in the upright position ready for exposure no such covering is necessary. Walter Tully, 76, Benedict Street, Glastonbury.

**ENLARGER.**—No. 24,101. The invention relates to the negative carrier of the enlarger, and consists in the provision of means for moving the carrier in all directions. Gaston Clement and George Gilmer, 140, Faubourg St. Martin, Paris, France; and 1, 2, and 3, Holborn Circus, London, E.C.

## New Books.

**Penrose's Pictorial Annual.**—The Process Year Book for 1906-7." London: Penrose and Co. 5s.

It is meant in no disparagement when we state that this yearly visitor carries out its principal title more efficiently and, if we may use the term, more sumptuously than it does its sub-title. Literary matter, such, plays in this volume a less important part than the illustrations. Many will not be disposed to quarrel with it on this score, any slight disappointment will be amply compensated by the wealth and beauty of the illustrations in colour, half-tone and photogravure. The illustrations certainly form, as in previous volumes, a good index as to the present status of photo-mechanical work.

Amongst the most notable of the articles are "What we Think of Direct Photography in Colours," by Alcide du Haaron; "The Direct Copying of Plans by Photo-Zincography," by R. B. Fishenden; "Direct Three-Colour Work on Dry Plates," by A. J. Bull; "Photography and the Stage," by Jas. E. Gould; and "Indirect Colour Reproduction," by Sydney A. Pitcher.

It is almost unnecessary to state that the printing and general set-up of the work are excellent, and our congratulations are extended to the editor, Mr. William Gamble, and to all these, not omitting the printers, Messrs. Percy Lund and Co., who have contributed this comprehensive demonstration of process work.

The sales of pictures at the Southampton Exhibition amounted, we are informed, to £38 8s. 6d.

**MESSRS. GRIFFIN en Fête.**—The members of the "Gramme" Recreation Club (John J. Griffin and Sons, Ltd.) held their fourth grand chemian concert in the International Hall, at the Café Monaco, on Saturday last, with T. McKinnon Wood, Esq., M.P., in the chair. There was a good attendance, and a most excellent programme of vocal and instrumental music had been provided, under the direction of Mr. Wilson. The "Gramme" Orchestra, who rendered several selections during the evening, were congratulated upon the success of their first performance in public. Mrs. McKinnon Wood very kindly distributed the prizes gained by members of the club, which were as follows:—Swimming: 1st (shield and medal), H. Gemmell; 2nd (medal), T. Sampson; 3rd (medal), A. Foskett. Novices race (medal), W. Colls. Cricket: Batting championship, A. Budd (cup and medal); bowling championship, C. G. Shipton (cup and mounted medal); consolation prize, batting (bat with engraved shield).

## New Apparatus, &c.

**The Beck  $f/3$  Studio Lens.** Made by R. and J. Beck, Ltd., 68, Cornhill, London, E.C.

Messrs. R. and J. Beck have submitted to us one of their studio lenses, Series I., No. 2, of 6-in. focal length and full aperture of  $f/3$ . This is a non-symmetrical doubler, formed of two uncemented combinations. It covers a circle of about five inches diameter, and should give very good results on any plate under quarter-plate size. The definition in the centre of the plate is excellent, and at  $f/3$  the falling off in towards the margins is not nearly so great as we expected to find it. Astigmatism is small in amount, distortion is not apparent, and the field is only slightly concave towards the object. This should be a very useful instrument for carte size portraiture. A comparison between this lens and an old Petzval lens of the same focal length shows a most marked superiority in the marginal definition. The new lens at  $f/3$  is far superior to the old at  $f/4$  in this respect, while in the centre of the image the definition is nearly, if not quite, as good. We need hardly point out that for fine central definition a Petzval portrait lens of the old type cannot well be beaten, and that few modern lenses come up to the same standard. In many cases perfect central definition has to be sacrificed to secure suitable marginal corrections.

**The "Holostigmat" Convertible Lens, Series 1A.** Made by Watson and Sons, 313, Holborn, London, W.C.

This new lens is an anastigmat of remarkable rapidity, the full apertures being  $f/4.6$  and  $f/4.8$ . The series includes "holo-symmetrical" and "hemi-symmetrical" lenses, or, in other words, doublets formed of two combinations of equal focal length and of combinations of unequal focal length. The one submitted to us is of the former type, the single combinations being each of 12in. focal length, and the doublet 7½ins. Each component is a triple cemented combination with only two reflecting surfaces, hence the fog due to double reflection is reduced to a minimum. It is claimed that the aperture is constant, which note we are very pleased to see, as purchasers are so seldom informed on this matter. The particular lens we have examined, No. 8 of the series, is listed to cover a half-plate, but its angle being about 75 degrees, it will cover a larger plate when stopped down. Tested in a half-plate camera, the result at full aperture,  $f/4.6$ , somewhat surprised us, for the definition over the whole plate was excellent for such an aperture, being perfect in the centre and falling off only slightly towards the margins. The field was very slightly curved, and the corrections, as regards aberration, of a very high order, even near the margins. At the more generally used,  $f/8$  aperture there was still less aberration, and at  $f/11$  the plate seemed to be covered quite perfectly to the margins. There appears to be a slight alteration of focal length when the stop is closed down from  $f/4.6$  to  $f/5.6$ , but from that aperture downwards the focus seems constant. It must be understood that these comments apply to critical tests of the lens, and its behaviour under them shows it to be an instrument of a very high degree of perfection.

The single combinations also work excellently at full aperture of  $f/8.5$ , and can be used either behind or in front of the stop. In the latter position the extension of the camera, from flange to focussing screen, is only 9½ inches, or 2½ inches less than the focal length—another practical advantage.

The mount has a scale of apertures for the complete doublet and one for the single combination, hence there is no trouble whatever in the adjustment of aperture. There can be no doubt that this is a very fine lens, and one that should be invaluable for focal-plane work and all branches of photography where the finest definition is required at a large aperture.

The lens is made with the separate combination of equal or of dissimilar focal length, the quarter-plate lens being obtainable as a 5½-inch focus, with the separate combinations, each 8½ inches focal length. The price of the lens in the first case is £8 12s. 6d.; in the second, £7 15s.; and similar facilities are offered by Messrs. Watson in the various sizes. The longest focus obtainable is 14½ inches, suitable for a 12 by 10 plate, and costing £42. The lenses of the longer focal length are of the same large aperture as the smaller ones.

## New Materials.

Wellington "Carbon-Surface" Bromide" Paper. Made by Wellington and Ward, Elstree, Herts.

We find it difficult to review new printing materials, the special claim of which, to the notice of our readers, is the surface-texture of finished print, and the new bromide paper introduced by Messrs. Wellington and Ward comes in this category. The prints obtained on the paper submitted to us are not exactly glossy nor are they matt. Their surface is that of an indescribable medium between the two, to which the term "carbon" may certainly be applied without misleading those who are familiar with what is usually understood by that term by practised users of the pigimentary process. That the addition should be made to the series of Wellington papers will be assuredly appreciated by users of the bands already on the market. The new paper is uniform in price with these, and it leaves Messrs. Wellington and Ward's customers with no ground for complaint that they are unprovided with all the varieties of printing material which a photographer, be he ever so exigent, can demand.

Ilford Gaslight Lantern Plates. Made by Ilford, Ltd., Ilford, E.

Although the lantern plates issued with the Ilford trade mark have been known for years past in the shape of the "Special" and "Alpha" brands—the latter an emulsion particularly favoured for warm tones—it is only now that the Ilford Company has brought upon the market a lantern plate possessing the two popular features of gaslight development and vigorous black tone. This has been done in the plate of which we have now to speak, and we can say at once that in acceding to the popular demand for a product with these conveniences the Ilford Company has not abated one iota of its zeal for the high quality of its manufactures. From the trial of the plates it would seem that the emulsion is on the lines of the gaslight paper, to which we were able to extend a favourable notice two weeks ago; and indeed it is a natural supposition that, having worked out a product of the character of the materials, any firm should wish to extend its application to glass as well as to paper. Whether this be so or not, the fact remains that, with the new gaslight plate, it is easy to obtain lantern slides possessing the vigour and purity of lights which characterise the paper of the same firm and class. We found very great latitude in exposure, inasmuch that it was possible to give twice and more the exposure and still to obtain excellent slides by removing the excessive density by a reducer. On this account the plates should particularly please beginners in slide-making, yet we believe also that the fine quality of the deposit will equally recommend them to connoisseurs.

## CATALOGUES AND TRADE NOTICES.

"HOUGHTONS' QUARTERLY."—The current issue of this publication of Messrs. Houghtons, Ltd., deals with the firm's recent introductions. The "Quarterly" is sent to all applicants individually or to the trade for distribution.

MESSRS. J. H. DALLMEYER, LTD., ask us to notify that the exhibition of American portraiture, now arranged at 25, Newman Street, is open Saturdays until 2 o'clock.

THE Latest Art Gallery.—Those who are interested in the modern painter's art will be pleased by a visit to the International Art Gallery, at 14, King William Street, Trafalgar Square. There is just a tinge of infringement in its title, which makes use of a phrase already well established by an annual show of first importance in London. However, since the exhibits include examples by leading men in France, Holland, and England, no one can grumble. The standard of merit is very high indeed in these works; but it nowhere reaches the highest point of any one man's reputation. It is refreshing to see how art progresses in other countries, and especially to see how our home scenes are interpreted by such talented workers as Houbroon and Witsen, for example. We always welcome the international spirit in art, photographic or otherwise, for we believe there is no better agency for advancement.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Dec.	Name of Society.	Subject.
21.....	West London Photo. Society...	"Ozobrome." Demonstrated. O. J. Bartlett
21.....	Cardiff Photo. Society .....	"Holiday Reminiscences"
24.....	Stafford Photo. Society .....	"Photography 1906 Prize Slides."
25.....	Royal Photographic Society ..	No Meeting.
26.....	Worthing Camera Club .....	Camera Outing.

### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the committee was held at the Royal Photographic Society, 66, Russell Square, on Friday, the 14th inst. Present: Messrs. F. A. Bridge, Alfred Ellis, S. H. Fry, Martin Jacolette, H. E. Hull, A. Mackie, Edgar Scannell, and Lang Sims. Mr. Martin Jacolette, president.

Seven photographers who had applied for membership since the last committee meeting were admitted.

The hon. treasurer reported that the number of members at the time of the publication of the "Handbook" in May last was 519. Since then 14 had resigned and 70 new members had been admitted, making the membership to date 757. He also reported that the number of members who had paid their subscriptions up to date was 523, and the balance in hand was £190. It was decided that £10 be invested in Consols.

The hon. secretary drew attention to a letter appearing in the correspondence columns of the *BRITISH JOURNAL OF PHOTOGRAPHY* from Mr. A. Doust, on the subject of "Enlargement Canvassing" showing that, as the committee had consistently advised the members, a local photographer could effectually expose the methods of free portrait and other fraudulent canvassers, and put a stop to the business without great difficulty or expense.

A letter was read from the hon. secretary of the Transvaal Professional Photographers' Association announcing the establishment of the association, and inquiring what steps to take to become affiliated to the home association. The rules of the new association were found to be based on those of the P.P.A., except that the subscription was £4 per annum, and it appears that assistants as well as employers were eligible for membership. The hon. secretary was instructed to write and congratulate the members of the Transvaal P.P.A. on their institution, and to express the pleasure the committee would have in constituting their association and corresponding associations, and in working in harmony with it in the interests of professional photography in both countries. The hon. secretary read a letter from a member on the subject of the necessity of properly specifying the property intended to be covered by fire insurance. It was suggested that attention should be directed to the point in the "General Information" column of the next "Handbook."

CROYDON CAMERA CLUB.—Mr. J. Bawcomb lectured last week on "Photo-micrography." He showed his apparatus set up, pointing out the necessity of having alignment through the system. If the object is transparent it may be illuminated by transmitted light, but, if opaque a reflector must be used to throw light on the upper surface, which necessitates much longer exposure. The eye-piece should be used on the microscope whenever possible, as without it there is a good deal of reflected light from the sides of the tube, even when properly blackened. A lining of black velvet will prevent this. Focussing is roughly performed on the ground glass, and finally, with a focussing glass applied to a clear spot, made by attaching a cover glass with Canada balsam, to the screen, the fine adjustment of the microscope being used. Mr. Bawcomb advised beginners not to attempt high powers, for several reasons. With high power vibration is the great trouble, and during the long exposure required perhaps four hours, a change of temperature may upset the adjustment, especially as with high powers the depth of focus is practically nil. Again, a photograph of the whole of an insect, or object, is generally speaking, of more interest than a small portion very highly magnified. For general work a 1-inch objective was recommended as most useful, together with an A and B eye-piece. An eye-piece of too high a power magnifies, but destroys definition. The objective must be achromatic, but need not be apochromatic, which increases their cost very greatly. English made objectives are as good

foreign, and are corrected for 10-inch tubes. The use of an orthochromatic plate and filter would to a great degree compensate for lenses that was not highly achromatic. Plates should be backed. One of the greatest difficulties is to get contrast, when objects are more or less transparent; therefore hydroquinone developer is advisable, and full development must be given. When an object is stained and the background clear it is necessary to use a gelatine screen of the same colour as the object, in order to hold back the background, which otherwise would pass too much light and swamp the object. The polariscope is also useful for giving contrast to transparent objects. Mr. Bawcomb exposed and developed a plate before the members, but though the result showed too much vibration under the conditions it was not bad for a magnification of 500 times. Dr. Reed, in reply to an inquiry from the lecturer, gave an interesting explanation of the fact that an erythrosin plate was preferable for work to a panchromatic. Taking the spectrum curves shown by the wedge spectroscope for the two plates, the highest points of the curve represent the maxima and the lowest, the minima of sensitiveness. The panchromatic has some half dozen maxima between the blue and the red, and the yellow filter will only cut off the blue; but the erythrosin (or commercial iso plate) has but two maxima, the blue and the yellow green. A filter, such as the yellow, will cut out practically all the blue, leaving the yellow rays only to form the image on the plate, practically monochromatic light, and consequently a sharper image.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held December 13. Mr. E. T. Wright in the chair. Mr. Oliver S. Dawson lectured upon "Colour Printing in an Ordinary Frame and the Dischner Natural Backgrounds." He said that colour photography was at present in the air with both amateur and professional photographers, many of the older professionals being tired of the older methods of things, and there were at present three methods of producing colour photographs. First, by colouring or painting a photographic negative; second, by the three-plate and three-printing process; and third, the purely photographic negative and one printing; and it was the latter to which he wished to draw attention. It was, he said, a method of producing a colour print direct from a coloured positive, the paper used being invented by Drs. J. H. Smith and W. Merckens. The process was known as the "bleach-out." Before exposing to light the paper was of a very dark colour, but the light turned it white. Upon being placed under a coloured positive, and printed, the paper assumed the same colour as the positive, and upon after printing only required fixing and drying. The paper had been greatly improved lately, inasmuch as the special solution formerly used upon blotting at the back of the paper at the back to bring out certain colours, was no longer required. The "Dischner" backgrounds were explained and results obtained by their use exhibited. A vote of thanks to Mr. Dawson brought the evening to a close.

## Commercial & Legal Intelligence.

TENANCY RIGHTS.—At the Leeds Assizes last week the case came before the Lord Chief Justice in which Werner Gothard, photographer, of Leeds and Barnsley, brought an action against the Royal Exchange Company, Leeds, Ltd., for breach of covenant. Mr. F. Randall Atkinson, K.C., and Mr. H. T. Waddy were for the plaintiff, and Mr. J. A. Compston represented the defendants. The plaintiff's case was that in June, 1902, he leased from the defendants a suite of rooms in the top floor of the Exchange Buildings, at the junction of Boar Lane and Park Row, and one of the terms of the lease was that he should have "a right of way during business hours through the main entrance hall and staircase by means of the passage and stairs." He was also to have the right to fix approved show-cases at main entrance. Some differences had arisen with regard to the show-cases, but since October, 1903, the entrance gates of the building had been closed at six o'clock on ordinary days and two o'clock on Saturdays. This, the plaintiff contended, made his tenancy of the rooms almost valueless, as he did the greater part of his business on Saturday afternoons and on summer evenings. Mr. Compston, in opening the case for the defendants, contended that

the phrase "business hours" meant the ordinary business hours of the tenants of the building; and that objection was taken to the show-cases submitted by the plaintiff on the ground that they were not artistic enough. Thomas H. Hussey, chairman of directors of the defendant company, and Henry R. Cousins, solicitor to the company, bore out counsel's opening statement with regard to the show-cases. J. Rosemont, photographer, of Bond Street, Leeds, said that persons in his business in the centre of Leeds would not, in his opinion, have many customers on Saturday afternoons and on week nights. He admitted, however, that he sometimes kept his premises open until five o'clock on Saturdays, and added that Bond Street was like a wilderness at certain times on Saturday afternoon. In summing up, his Lordship commented upon the conduct of the negotiations with the plaintiff by the defendants' solicitor, and said that the jury had to consider whether the plaintiff had been fairly dealt with. It seemed clear from the evidence, and from a commonsense view of the case, that a photographer would want to use his rooms at such hours as were most profitable, and at the commencement of his tenancy he did use the premises as he desired until the new arrangement was made with regard to closing the gates. He (the judge) could not see how the defendants' solicitor could have arrived at the conclusion that the plaintiff would not wish to use the rooms during the hours that photographers commonly used them. The jury, after an absence of about an hour, returned a verdict for the plaintiff, assessing the damages at £650. Stay of execution was granted, but his Lordship pointed out that plaintiff was entitled to an injunction against keeping the gate closed during reasonable hours, 9 a.m. to 8 p.m.

BREACH OF PROMISE OF MARRIAGE.—The manageress of a Leeds studio, Miss A. E. Fleck, was awarded £250 damages at the Leeds Assizes last week in an action brought against Mr. Werner Gothard, proprietor of the studio, for breach of promise of marriage.

PHOTOGRAPHER "Wanted."—At the Halifax Borough Court last Saturday, a middle-aged man, giving the name of William Williams, and describing himself as a photographer, of no fixed abode, was charged with having in April last obtained the sum of £2 by false pretences from Ernest William Nelson, of Leeds. The accused pleaded guilty. The Chief Constable (Mr. Richardson), however, said it would take time to prepare the charge they were going to prefer, and he asked for a remand. The prisoner was "wanted" by the police at Hereford, St. Helens, and other towns, in connection with frauds through a photographic paper. The remand was granted.

### NEW COMPANIES.

FERRIS FILMS, LTD.—Registered December 7. Capital £100,000, in £1 shares. Objects: To adopt an agreement with the D. U. B. Syndicate, Ltd.; to work the secret process for the manufacture of photographic films referred to therein; and to carry on the business of manufacturers of and dealers in photographic requisites of all kinds, etc. The signatories are: E. N. Adler, J. A. Belcroix, J. Bon, L. Urban, P. Casparis, E. M. S. Perowne, and C. S. Blackmore. No initial public issue. The first directors (to number not less than two nor more than five) are not named. Qualification, 200 shares. Remuneration, £400 per annum and 2 per cent. of the net profits, divisible.

BOLT COURT SCHOOL.—Mr. W. J. Smith has been appointed by the Council as second assistant to the principal.

OUR contemporary, "Black and White," is offering an India-tint print of the painting "Cornered," to direct annual subscribers.

MR. W. DOUGR writes: "Owing to the busy time and the holidays being near, I have decided to leave all suggestions until after Christmas, when I hope to give several suggestions, also extracts, from several letters. I am still open to receive any names and suggestions during the holidays."

DR. EDER announces, in the "Korrespondenz," that the German Patent Office has refused the application for a patent to Mr. C. G. Zander for his four-colour process, on the ground that the principles were previously published by Eder (Vorträge des Vereines zur Verbreitung Naturwissenschaftlicher Kenntnisse, in Vienna, 36 Jahrg., Heft. 9, p. 13), and by von Hübl (Die Dreifarben-photographie, Halle a. S. 1st ed., 1897, p. 77), in such a manner that any expert could carry them out.

## Correspondence.

- \**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- \**We do not undertake responsibility for the opinions expressed by our correspondents.*

### REGIMENTAL MOUNTS.

To the Editors.

Gentlemen,—As a subscriber to your valuable paper I am enlisting your help in a small matter. Could you inform me the makers of "Regimental Mounts," decorated with the colours and badges, etc., of the different regiments?

I have applied to the dealers who used to stock them, and other large wholesale houses as well, but merely get the reply, "We do not stock them now."—I remain, your regular subscriber,

BUSINESSLIKE.

[We do not know the mounts, but we shall be happy to pass on any communications to our correspondent.—Eds. B.J.P.]

### THE MISSING WORD.

To the Editors.

Gentlemen,—Your note on p. 983 of last week's issue emboldens me to suggest that the necessary and truly descriptive word may be compounded from the four roots—"tele," "icon," "electro," and "graph." Thus, teleconelectrograph. For the sake of euphony we may drop the final e of tele, and should then have the term telicon-electrograph, which, whilst somewhat of a mouthful, is sound philologically.

An alternative we may transpose these roots and use in the following order "tele," "electro," "iconograph," and submitting this to the same process of euphonic excision, we obtain teletriconograph.

As to which is the better or worse, and whether one or neither be satisfactory, must be left to others.

The terminal words of both can be defended, as "electrograph" is defined in the Standard Dictionary as: 1. The linear record of an electrometer. 2. An apparatus for tracing a design to the electro-etched for use in printing wall paper, calico, etc., and "iconograph" is "an image or likeness of anything produced by the graphic or plastic arts."

The first word, "telicon-electrograph," would possibly be the more descriptive, as it conveys the idea of a distant picture by the conjunction of "tele" and "icon," and this is the essential point, both in Professor Korn's and M. Belin's discoveries.

To attempt to differentiate between the two processes would, if M. Belin's statement that he uses no photograph be confirmed, necessitate the introduction of the term photo somewhere to describe Professor Korn's method, and I do not attempt this in any seriousness, for I do not want to be saddled with such an offspring as telephoticon-electrograph.—Yours faithfully,

A. GASCOIGNE.

London, E.C.

### MR. BENNETT AND TIME DEVELOPMENT.

To the Editors.

Gentlemen,—In the discussion following the lecture at the Croydon Camera Club, the case in opposition to Mr. Bennett's well-known views appears to have been ably represented. I have no intention therefore to enter into a discussion on the lecturer's arguments.

But his statement of the basis of time development appears to me to be so imperfect that I feel bound to disown it. Here is the quotation: "Time Development methods, according to Mr. Bennett, are based on two assumptions:—

"(a) That all subjects will yield uniform negatives with uniform development.

"(b) That no alteration in the composition of the developer will produce any other result than that given by the unmodified developer."

As far as I can understand the meaning of English, the above two "assumptions" are crude and incorrect, although they could be made truthful by rewording and extending.

Moreover, the ideas which are here attempted to be conveyed are not the primary basis of time development. The true basis of time development, as I understand it, is that at an early "time" of

development there is little or no contrast between the tones; that at a very late "time" of development there is far too much contrast between the tones; and that at some intermediate "time" of development there is just such amount of contrast that the tones of the subject are not extended beyond the capacity of the printing paper, but rendered by a truthful degree of contrast.

Of course, this is not all, but it is the basis, the starting point, both for simple time development and for factorial development.—Yours truly,

ALFRED WATKINS.

Hereford.

## News and Notes.

**THE Scottish National Salon.**—The prospectus of the fourth Scottish National Salon, promoted by the Scottish Photographic Federation, now comprising 43 societies, has just been issued. The Salon, which appeals to all Scottish photographers, is to be held this season in Paisley, in the Art Gallery of the Museum, from February 23 till March 16. Paisley, apart from its close proximity to Glasgow (six miles), and easy accessibility from all parts, is a capital centre, it having within its boundaries a population sufficient to justify the federation in anticipating a most successful exhibition. The Scottish Salon, it may be said, is confined to the work of photographers resident in Scotland, and to the work of Scots residing abroad. Two eminent workers not thus qualified are each year invited to send examples of their work, and this year the Salon committee have been fortunate in securing Mr. C. F. Inston, who will represent England, and Herr Masuren, Halle, who will send a representative collection of German and Austrian work. All photographs entered, excepting the invited work, are submitted to a Board of Selection, the Board for this Salon being J. Craig Annan, W. Crooke, Patrick Downie, R.S.W., Alex. Keighley, and James Patrick. An art union has been promoted in connection with the Salon, to encourage the sale of work by prominent workers. The arrangements are in the hands of a local committee, which meets under the chairmanship of Sir John Ure Primrose, Bart., LL.D. All communications should be made to the hon. secretary, Robert Milne, Linnvale, Potterhill, Paisley, who will be glad to forward prospectuses on application.

**INCANDESCENT MANTLES.**—In reference to the announcement of the improvements in mantles, made in the "Times" Engineering Supplement, and reported in the B.J.P. some week or two ago, mention is made in the "Times" Engineering Supplement of December 12 of a British new mantle, the invention of Mr. John H. Ladd, and manufactured by the Laddite Incandescent Mantle Company, Surbiton. In this case there is nothing special in the manufacture of the fabric of the mantle, which is knitted from ramie fibre in the usual way, and its excellence in respect of toughness and light-giving power is due to the solution in which the fabric is steeped. The composition of this solution, which, of course, consists largely of the nitrates of thorium and cerium, depends on the presence therein of an extra ingredient which the inventor has called "Laddite." The effect of this addition is not only to impart a remarkable amount of toughness to the otherwise fragile ash which serves as the framework for the deposits of the thorium and ceria, but it would seem also to render the ceria much less volatile and to cause the oxides to adhere more strongly to the residue left by the fibre. Moreover, under the influence of intense heat, the light rises steadily in brilliancy. Mantles of this kind which have been tested by public authorities have been found uninjured after burning for upwards of 2,500 hours, and Mr. Ladd claims for his ordinary mantles a life of at least 2,000 hours. The Laddite mantles, even after long use, can be removed from their supports and can be handled. As an illustration of their toughness, one of these mantles, which had been burning for upwards of 2,000 hours, was laid on its side and was found to be capable of supporting two bronze pennies. From authoritative tests, the statements as to the durability and high illuminating power of the Laddite mantles are fully confirmed, while shock tests on the vibrating apparatus are greatly in their favour, for whereas the ordinary mantle is destroyed by 30 or 40 shocks, the improved mantle has resisted 500 shocks without damage. In one of the tests for illuminating power the loss in light after burning for 1,400 hours was only 2 per cent., and it is stated that even this small diminution in brilliancy was probably caused by a slight injury to the mantle arising from its removal from the burner.

## Answers to Correspondents.

- All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPH REGISTERED:—

F. G. Bright, Herbert Villa, Salcombe, South Devon. Photograph of H.M. Transport "Reva."

TRICK PHOTO.—Messrs. Marshall Brookes, Harp Alley, Farringdon Street, E.C., are the publishers.

DARK ROOM.—We are at a loss to recommend a better solvent. Acids will have more effect in breaking up the deposit, but at the risk of ruining the joints of the pipes. Sulphuric or acetic might be tried, but we should prefer to call in a plumber.

J. S. (Stratford).—Messrs. Sichel and Co.; 52, Bunhill Row, E.C., and Messrs. W. Butcher and Sons, Farringdon Avenue, E.C., supply outfits for titles. For quantities it is usual to set up in type or draw details, make a negative, and strip off on to the portrait negative.

DRYING CUPBOARD, ETC.—(1) What size would you advise me to have my drying cupboard for bathed plates, for, say, not more than twelve half-plates? Also (2) what is the highest temperature the plates will stand without risk of injury? (3) Am I right in supposing that the Pinatype process of three-colour printing and Sanger-Shepherd's demand the same character negative?—F. B. W.

(1) The size will entirely depend upon the number of plates to be dried, and it can be easily calculated by allowing for four inches between the plates, which should be placed at an angle of 45 degrees. They can, of course, be placed in two rows, on one shelf or on two shelves. It is an advantage to have a fairly roomy cupboard, as greater evenness of drying is obtained. (2) The temperature should not exceed 85 deg. Fahr., and 80 deg. is better, with a good current of air; lower temperature is quite sufficient to dry the plates in about six hours. (3) Yes, soft thin negatives, which will print even in the high lights, should be aimed for.

Y. Z.—The commercial cards produced in large quantities are toned in the hypo alum bath, and on some glossy papers the tone is a very good imitation of P.O.P. The sulphide processes are used on a smaller scale, but not to the same extent, we think. We should advise you to try hypo alum in conjunction with a make of bromide paper, for which that process is recommended; but you must keep the process working in large bulk to ensure regularity of output.

BROMIDE.—(1) Given a plucky negative from which a soft print is required, would you print it in direct sunlight or in the shade? (2) Similarly in a bromide print, would you hold the frame nearer to, or further from, the light to obtain a soft print, allowing, of course, for the difference of exposure? (3) Given two negatives of the same apparent density, the one a blue-black and the other having a slight yellow colour, which would give the softer print?—GLADYS.

(1) In the sunlight. (2) Nearer. (3) Pluckier results will be obtained from yellow stained negative.

REGISTRATION.—Your supposition is correct. The design should be registered without the photographic view. These latter should be registered separately, if it is desired to protect them.

RUTT.—Try an eight-inch piece on each side.

NEGATIVES.—(1) Which is the best way of making a negative from a transparency? I have tried one way by placing the plate to be exposed in contact with transparency in printing frame exactly the same way as I did the transparency. Another way I tried was to put negative and plate in contact and then in dark slide and exposed through the lens, the same as taking a view with the camera looking to the sky. This way was also a failure. In both ways the negatives were so fearfully fogged-looking and flat, with no brilliance. (2) Also, why it is that in films I am unable to get writing matter not so transparent of the letters like an ordinary glass plate if a special kind of developer would be the same result. (3) What developer is the best to get an ordinary plate as hard and black as I possibly can?—OCTOBUS.

(1) Method 1 is liable to give a little fog or veil, but not the excessive amount you describe. Try a black cut-out mask on the transparency to cut out the edges, and use a printing frame a size larger, this to prevent fogging from the edges of the glass. But we suspect the real cause is over-exposure. (2) An emulsion of a "softer" working character is frequently used. (3) A strong hydroquinone developer, either of those on page 953 of the "Almanac," 1907, will give good results, on plates and greater contrast or films.

VARIOUS.—(1) Do you know of any method of rendering bichromated gelatine, gum, etc., more sensitive to the action of light than it is in the ordinary practise of carbon printing? Can you suggest, to one with a slight knowledge of chemistry, any experiments with this object in view? (2) Can you suggest any chemical or physical means to secure greater rapidity in the "continuing action of light" with colloids sensitised with bichromate? (3) What is the known or presumed action (in words, not symbols) of hydrogen peroxide in producing catalysis or transference of light action? (4) What metal salts, other than silver, platinum, iron, are sensitive to light, and what is their proportionate sensitiveness to silver bromide? (5) Can you tell me what colloid has the greatest amount of expansion under the influence of heat?—COLLOID.

(1) Bichromate of ammonia is said, by some, to give greater sensitiveness than the potash salt. The larger the proportion of the bichromate the more sensitive will be the tissue, and the shorter the time it will keep in good working condition after sensitising. (2) Moisture and heat greatly increase the action. If the exposed tissue be kept in a moist atmosphere, at a temperature of from 75 deg. to 80 deg. Fahr., the action goes on rapidly, and in this way the necessary exposure can be greatly curtailed. (3) Hydrogen peroxide is not a catalyst but the substance used in catatype processes, which is readily decomposed by the catalytic action of, say, manganese peroxide. The latter oxidises the peroxide, is thereby reduced, and can be reoxidised for further action. (4) The bichromate salts are the only others, in addition to iron and silver, of practical importance. We should not include platinum salts, the photo-sensitiveness of which is very small. As regards relative sensitiveness, well, you have a range from a rapid emulsion to blue print paper. (5) We know of no colloids that expand with heat when in the dry state. They all contract with heat when dry.

CARBON PICTURES ON METAL.—Can you give me a formula for making a carbon transfer adhere to metal so as to stand the weather without peeling? And if it would be advisable to varnish it, what varnish to use?—F. O. R.

Clean the metal thoroughly. Then immerse it, and the print on the flexible support, in the following warm solution:—Nelson's No. 1 gelatine, one ounce; water, one pint; when dissolved, add fifteen grains of chrome alum in hot water. Add this slowly and with vigorous stirring. When the print is softened in this bring in contact with the metal and squeegee together. It is possible, if the picture is then varnished with "Zapon" varnish, it will stand the weather for a time. This

varnish may be had from the Crane Chemical Company, Birmingham. It is substantially a celluloid varnish. Perhaps a better varnish would be a copal stoving varnish, if it were "stoved"—that is, heated in a japanner's oven, or the kitchen oven might be used for small work. This would probably stand the weather better than the first-named varnish.

**PUZZLE.**—1. The over-exposure mentioned would scarcely have been sufficient to cause the reversal. We should say the plate might easily have been under-exposed. The most probable cause of the reversed appearance is fogging by long development. We have frequently seen similar effects when plates, under-exposed in some cases, have been forced to bring out all possible detail. We ascribe it to the greater amount of fog, proportionately, in the shadows of the subject, causing these portions to print much lighter than they should. This effect can be seen in the photograph you have sent. 2. There is no remedy.

**THE FACTORY ACTS.**—I should feel greatly obliged to you if you would let me know in what way the Factory Act applies to the ordinary photographic studio. At this season of the year, owing to heavy pressure of business and poor light, we are obliged to work on late to cope with rush orders. I understand from the inspector that according to this Act we can, as a staff, only work on until eight o'clock in the evening, and must close one half-day in the week; anyway, assistants must be let off at four o'clock. Of course, these hours are longer than we should work at ordinary times, and my assistants always have half-day, leaving at two o'clock, but taking it in turns, except during December. I am not quite sure, but am inclined to think it only affects those under eighteen.—**ANXIORS.**

The Factory Acts apply to photographers just as they do to all other businesses where a number of hands are employed, and you will have to abide by them. The hands must have the bank holidays and leave off on Saturday at four o'clock. You may get permission to change the Saturday to another day, when the workrooms must be closed at four o'clock. You may, also get permission to work a few days during the year overtime by giving notice to the inspector of the district.

**PYRO-SODA DEVELOPER.**—I have been trying the pyro developer described on pp. 763 and 782 of the B.J. for September 28 and October 5. I made up 20 oz. according to the first formula, viz.

Pyro .....	160 gr.
Soda sulphite .....	2 oz.
Potass. metabisulphite .....	½ oz.
Water to .....	20 oz.

This developer, with me, works very slowly, and after prolonged development does not give any density worth mentioning. The par. on p. 782 of the B.J. for October 5 states that some errors crept into the first note, and recommends a stock solution of—

Soda sulphite .....	4 oz.
Potass. metabisulphite .....	1 oz.
Water to .....	20 oz.

10 oz. of this is to be taken, and 10 oz. of water in which 20 gr. 160 gr. of pyro is to be dissolved. This, however, is exactly the formula in the first note, and is what I have used. I should like to know whether this is really the formula you recommend, and whether it should work so slowly and fail to give density. Adding more soda carb. had only the effect of fogging the whole surface of the plates, rebates and all.—**REX.**

The correction referred to applied only to the stock solution of neutral sulphite. The developer itself was correctly given. Using 4 grains per ounce full density should be attained in something under ten minutes at normal temperature. We have commented on the slowness of this developer several times. It was given as a specimen of a non-staining pyro-soda developer that would keep. Whether a rapid developer of the same class can be compounded has yet to be determined.

**TENANCY AGREEMENT.**—I have taken a private dwelling-house from October last, and have signed an agreement of tenancy of same for one year, but the landlord insists on me paying my rent weekly, which I have done since occupying the house, and since then, here I find the house is so damp that not only our furni-

ture, etc., is suffering thereby, but my wife and family's health is also suffering, and we wish to move out as early as possible. Can I do so without being liable for a year's rent? Seeing that the landlord insists on me paying a weekly rent do I become a weekly tenant thereby, and does this cancel my agreement as a yearly tenant, or does my agreement stand under any system of paying rent. The landlord knew that the house was damp before we entered, but never informed us, or we should not have taken it.—**M. M.**

You having signed an agreement for a year's tenancy, we expect you will have to hold the house for that period, unless you can prove that it is not habitable and injurious to health. The fact that you pay the rent weekly, we think, will not invalidate the agreement. You might, however, submit the question generally to a solicitor.

**WINDOW ATTRACTION.**—Would you kindly let me know of any mechanical toy suitable for the window of a photographer to cause a little attraction during the Christmas time.—**CAMERA.**

Apply to Messrs. Potter, shop fitters, Aldersgate Street, London, E.C.

**T. BURLIN.**—We do not quite see the connection between your stained whites and Mr. Carnegie's theory. The stain in question is most probably due to impure soda sulphide solution. This should be boiled and filtered before use. The stock solution must be a strong one, and it should be diluted immediately before use. The diluted solution will not keep at all. Bromine water will completely bleach the image, and the image will slowly reappear in daylight. The result, however, is very weak.

**CHROME ALUM FIXING BATH.**—Please give formula for addition of chrome alum and sulphite soda to fixing bath for plates.—**TROOPER.**

The following from the "Almanac" is a suitable formula:—

Sulphuric acid .....	1 drachm.
Water .....	2 oz.

Add the above to—

Sodium sulphite .....	2 oz.
Water .....	6 oz.

and pour the mixture into—

Hypo .....	1½ oz.
Water .....	48 oz.

Finally, add to the above mixture—

Chrome alum .....	1 oz.
Water .....	8 oz.

**COPYING FADED PRINT.**—I have a photograph that is much faded to copy for a customer. Can you give me the formula and how to treat it to get a copy of same.—**COPY.**

There is no satisfactory method of restoring a faded print, so you will have to copy it as it is. We should recommend you to employ an orthochromatic plate for the purpose. If the print is very yellow, much of the yellowness may be bleached by treating it with a rather dilute solution of bichloride of mercury—that is, supposing the photograph has been toned with gold. If not, the whole of the image will be bleached out. In copying, illuminate the picture by a strong side light.

**\* \* NOTICE TO ADVERTISEES.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The index to the BRITISH JOURNAL OF PHOTOGRAPHY for 1906, including the items of to-day's issue, is presented as an eight-page supplement.

A studio has now been placed at the disposal of members of the Blenheim Club. (P. 1037.)

Demonstrations of a new commercial self-developing plate have taken place in the North of England. (P. 1036.)

The medalled formula for a developer of warm tones on chloride lantern-plates is given on Page 1029.

Formulae for relief-effect prints are given on Page 1033.

A German chemist has recommended a delicate test for gelatine. (P. 1030.)

A printing-frame and bromide printer are among the patents of the week. (P. 1034.)

Pencil photographs, presumably a combination of photography and drawing, are said to be a boom at present in Paris. (P. 1033.)

An over-worked Society Secretary.—The publication of book-ings of the R.P.S. affiliation lectures has brought to light a society which has secured sixteen hired lectures for a six months' session. (P. 1022.)

"To retouch or not to retouch" proofs is discussed with other "proof" questions by an American contributor. (P. 1028.)

The discussion of Mr. de Graaf Hunter's paper on shutter speed testing, in which Sir William Abney, Mr. Conrad Beck, Mr. H. F. Purser, Mr. Horace Beck, and Mr. S. D. Chalmers took part, is given on Page 1031.

Mr. A. Lockett, in an article on "Measuring and Surveying by Photography," treats of the elementary principles upon which these applications of the camera are based. (P. 1024.)

## EX CATHEDRA.

### Our Hearty Reciprocations.

We must thank most sincerely all those friends and readers—a distinction without a difference, we hope—who have sent us Christmas greetings, many the product of their own photographic skill, and others equally evincing the possession of a refined taste in graphic art. These expressions of regard are as welcome to us as any missives which we receive in the whole course of the year, and we would tender to the senders our brief, but none the less genuine, reciprocations. To all those who read these pages, whether known to us personally or not, we would wish a prosperous year throughout 1907.

\* \* \*

### The Index to the "Journal" for 1906.

We hope we may be pardoned for feeling some satisfaction with the index to the 1906 volume of THE BRITISH JOURNAL OF PHOTOGRAPHY, which is presented with the present issue, and includes the items occurring in all the fifty-two numbers of the past year. The compilation of an index which shall be as compact as possible while at the same time codifying the contents of the volume is a task which we have undertaken very seriously and systematically from the commencement of the year. A glance through the eight pages of over two thousand entries will, we hope, convince the reader that we have at any rate spared no pains to provide means of rapid reference to the contents of our text pages. It will be seen, also, that the first portion of the index is a subject one, and that the entries are sub-classified under such headings as

Backgrounds.	Gum-bichromate.
Bromide papers.	Lantern matters.
Cameras.	Leuses.
Carbon printing.	Orthochromatics.
Cinematographs.	P.O.P.
Collodion.	Postcards, picture.
Colour photography.	Self-toning papers.
Copyright.	Shutters.
Development.	Stereoscopy.

In each of these cases, all in the volume of permanent interest is indexed in alphabetical order, and not only that, but in the majority of instances there is an indication of the nature of information, whether a patent specification, letter to the editors, a society report, or a review of a book or of new apparatus. We believe we may assume that facilities such as these will be appreciated by everyone who has occasion to consult the volumes of the BRITISH JOURNAL, and we believe we may say, also, that the obligation to compile such an index is one which we, of all photographic journals, cannot disregard, inasmuch

as our contemporaries leave to us the publication of the papers and communications of permanent interest in the progress of photography. The preparation of an index worthy of the subject-matter is therefore a duty which we have at any rate endeavoured to discharge with all our might. Our readers, in their use of the index, must judge of the success which has attended our work.

\* \* \*

**Voice Photography.** According to the "Daily Telegraph," Dr. Morage, lecturing at the Sorbonne, Paris, one day last week on the Pollak-Virag system of multiple telegraphy, announced that he had devised a method of photographing the voice, and showed some results. The information given is somewhat meagre, but apparently the words are spoken into a microphone, and are registered in special wave-like signs somewhat akin to shorthand, which are photographed at the other end of the line. From such a bald statement but little can be gathered, but one can at least assume that the wave-like signs are due to the actual vibrations produced in some responsive medium by the voice. Somewhat similar announcements have been made in past years, for in 1901 Ruhmer utilised the variations of the well-known speaking arc lamp in connection with selenium cells, a telephone, and a cinematograph film, on which were recorded, through a narrow slit, wave-like signs similar to shorthand, which could in turn be used with a projection apparatus, another selenium cell, and telephone. In 1902 Cervenka obtained graphic records of sound waves, both on negative paper and plates, from which electrotypes in copper and vulcanite were subsequently obtained that could be used in conjunction with a gramophone or similar apparatus. In 1903 Ewald, of Strasburg, constructed his "camera acoustica," in which the sound waves were received by a vibratory membrane placed at the base of one of the ordinary tin gramophone trumpets, the vibrations being photographically recorded on a moving celluloid film.

#### The Misuse of Federation Lectures.

A short time ago we had a note on this subject, pointing out the want of wisdom shown by societies that practically fill their programmes with lectures obtained from outside sources. The list of bookings of the Affiliation lectures published in the "Photographic Journal" for December throws an interesting light on this matter. Thirty-two lectures being available, thirty-five out of sixty-six societies have secured only the modest number of one apiece. Nineteen societies have booked two lectures, six have taken three, four have taken four, and only one society has booked five lectures. But then, one society distinguishes itself above the rest by booking no fewer than sixteen lectures to fill a programme lasting only from December to May! The total period being less than five months, it is obvious that very few evenings are left to be filled by members of the society. There is a marked contrast between the programme of this society and that of the others, and it is very satisfactory to see that only one society out of sixty-six is apparently so helpless. Forty of the bookings are concerned with competition slides, which most societies naturally like to see, hence it is evident that many of the affiliated societies are quite resourceful enough to fill their own programmes. The biggest demand appears to be for lectures of the lantern show order. This may be indicative of a preference for light entertainment, but we are rather inclined to think that it shows ability on the part of the societies to provide their own technical lectures, and, if so, we can only look upon it as a healthy sign. In any case, lantern lectures

must be good if they are to serve as an attraction, and it is highly probable that many societies would never shun a really first-class set of slides if they depended entirely on their own resources. With the exception of the "awful example" we have referred to, it appears to be that the Affiliation societies use their privileges wisely. The members of other federations do no worse, the complaint made by the correspondent to whom we referred in our previous note would seem to have little foundation. It would be of interest to know how other lists of "booked" lectures compare with the one on which we have commented.

\* \* \*

#### Postcard Portraits.

The letter of a correspondent in our issue of last week raises a question that we have had in our mind for some little time past, namely the policy of photographers who supply portrait postcards at the ridiculously low price that many are now doing. A friend recently showed us a postcard portrait of himself taken a short time back at a fashionable seaside resort at the price of three for a shilling. This included the sitting, and a proof was submitted before the other two were printed. The portrait was the full size of the card, and, if not cut down, as it evidently was, would have been the full cabinet size. Technically the photograph was a good one, a fair specimen of middle class work. The size of the picture postcard,  $5\frac{1}{2}$  in. by  $3\frac{1}{2}$  in., is so close to the standard size of the trimmed cabinet portrait,  $5\frac{1}{2}$  in. by 4 in., that the public may well ask why it should be charged from twelve and sixpence to a guinea a dozen for the latter while the same photographers do what is practically the same size for from three and sixpence to five shillings a dozen, the only difference being the mounts. In many places where the postcard is not made a special feature of, the negatives are made on half-plates; therefore the production of the negative, and the retouching, costs the same as for the ordinary cabinet size portrait. This seems to us a matter that should receive the immediate attention of all professional photographers. The subject is one that might well be dealt with by the Professional Photographers' Association, but, unfortunately, that useful body has but little weight outside its own members. There is one way by which we can see that the growing evil might be checked. Let photographers as a body agree to supply as portrait postcards only such pictures as can be printed from quarter-plate negatives. Such pictures would not then clash with the ordinary cabinet portraits.

\* \* \*

#### Shabby Apparatus.

Last week we had something to say on the appearance of the studio and the effect it may produce on customers. What was then said with regard to the apparatus in the studio applies with equal force to that used out of doors. For example, supposing a photographer is commissioned, say, to take a group away from home; he unpacks his apparatus, which is clean and highly polished and the brass-work bright; the idea is at once created that it must be good and the work done with it must be correspondingly good. Whereas if it is shabby and dilapidated in appearance a doubt may arise in the minds of some that the results produced with it can be of a high order; although it may be far better for work than apparatus of a more showy character. First impressions go a long way with the public. Though outdoor apparatus necessarily receives more rough usage than that which never leaves the studio, there is no reason why, with care, it should not be kept in decent appearance. Soap and water and a little furniture polish will

work wonders and practically transform a shabby-looking apparatus into one that looks new and up-to-date. Again, some photographers in provincial places, at this season, make a feature of lantern entertainments. At these the appearance of the apparatus goes a long way with the audience. If, when it is uncovered, it shows a large amount of brightly lacquered brass-work a good impression is at once created, and the remark is sometimes heard, "That is a better thing than we had last time," while it may really be an inferior apparatus compared with the one used on the former occasion, and may not show the pictures to the same advantage.

#### Surveying with the Camera.

On another page we publish an article dealing with the important subject of "Measuring and Surveying by Photography." Some readers may remember a valuable and most complete paper on this matter, that was read before the Society of Arts some seasons ago, by Mr. Bridges-Lee, M.A. Few people seem to realise the fascination of this subject, or the fact that there is still much to be done in investigation and improvement of methods. For very accurate work, of course, special apparatus is required. The average camera is of little use, for the back and front must be rigidly parallel, and the exact point where the principal axis of the lens intersects the plate must be known. The first of these conditions is fulfilled in very few cameras, and it is difficult to fulfil it in any camera fitted with a focussing adjustment. The second condition cannot, of course, be ensured without perfect rigidity of all parts. A good deal of useful information can, however, be derived from negatives taken in an ordinary camera, if one has any accurate knowledge of the lens of plane perspective, and of their application to photographs; which are true plane perspective delineations if the lens is absolutely free from distortion. We have ourselves frequently taken snapshots with a Shew "Eclipse" camera, and from the results have calculated heights (and sometimes widths) with very satisfactory results; but the most difficult task we ever undertook in this way was the measurement of the height of a stone building from a bought photograph taken with an unknown lens that had been tilted somewhat, and also evidently gave slightly distorted results. In this particular case our method was to construct a scale on the image of the stone building, by perspective projection from the brick courses of a brick building visible some distance away. As the line of frontage was not straight, and the brick courses diminished in height towards the top of the building (owing to the distortion), this was a troublesome task. But there was no way of avoiding it, as we were in London and the building was in King's Lynn, and the measurement was urgently wanted. On a subsequent visit to King's Lynn we seized an opportunity of dropping a rope down the building to test our measurements, and, much to our surprise, we found that the measurements made from the photograph were in error to the extent of about 6 per cent., or no more than  $1\frac{1}{2}$  in. in 20 ft. This is an example of what can be done with the aid of a scale photographed at the same time as the building. One can have better scales than brick courses (though these are fairly reliable for rough dimensions) and we are much inclined to think that a couple of suitable scales (one vertical and one horizontal) in front of the camera would be of great value in facilitating future measurements. For land surveying very accurate apparatus, such as a photo-theodolite, is required, but for what may be described as sketch surveying and building surveying more can be done with an ordinary good camera and lens than many would deem possible.

#### ELECTRIC LIGHT INSTALLATIONS.

AN enquiry from a correspondent on the matter of installing electric light for portrait and group photography in an ordinary room, to which we briefly reply in our "Answers to Correspondents" column, suggests one or two points which we think may be usefully referred to at greater length. The room in question, being 17 ft. long by 12 ft. broad, is of ample size for the greater part of ordinary studio photography, though a width of 12 ft. will not allow groups of more than 12 or 15 people to be satisfactorily handled if pleasing arrangement of the figures is desired. As the height of the apartment, however, is only 11 ft. it is here that difficulty will arise both in making and working the installation.

Let us first consider the use of one or more of the enclosed arc lamps, to which reference has several times been made in these pages, and on the installation of which an epitomised note is printed in the "Almanac" for 1907 (*vide pp. 716-78*). Those who are familiar with these lamps or have seen illustrations of them will at once recognise that when suspended as near the ceiling as possible the arc and the positive carbon will be two feet to two feet six inches lower than the ceiling, or in a room of the height mentioned by our correspondent only eight feet six inches from the floor. This height would no doubt be sufficient for head and shoulder portrait work and for half lengths, but difficulties would arise when full length portraits, either sitting or standing, were attempted. The feet and floor would be something like twice as far from the light as the head, and, in consequence, the illumination would only be about one quarter as strong, the strength of the light varying, as is well known, inversely as the square of the distance.

In the case of single figures or groups of two or three a good deal may be done to get over this difficulty by using a large area of reflector, both on the same side of the sitter as that on which the lamp is suspended and also on the opposite or shadow side. The direct light from the lamp is diffused by the aid of a head-screen covered with tracing linen, but care is taken to allow the full power of the light to reach both reflectors so that the maximum of light is received and reflected again towards the feet and lower portions of the figure. For such reflectors there is nothing better than a surface approximating to white blotting-paper, but perhaps a cheap cartridge paper is easier to paste on to a canvas screen than the blotting-paper. Some of the cheap white lining papers which may be obtained from a house decorator are also satisfactory.

Where full length standing portraits of men are required the problem becomes more difficult, for the head of a six foot man will be within about a couple of feet of the height of the arc. This, of course, will be the case also if three-quarter length standing portraits are to be done, and they are quite a style often demanded. In order to obtain a source of light as high as possible, and higher than the arc itself, it would be well to place a dead white reflector on the upper part of the wall of the room extending from the ceiling downwards for, say, three feet. If this reflector could be sloped with its upper edge touching the ceiling and its lower edge touching the side wall so much the better, as it would then reflect a more direct light on to the sitter. The diffusing screen should also be placed as high as possible, and an opaque screen may sometimes be used to cut off some of the direct light from the lower part of the tracing linen diffuser, so that the whole of the effective illumination is from as high a point as possible.

When all these arrangements have been made for the effective management of the light from the photographic point of view we are still left to consider the matter from

the standpoint of the insurance companies. High-power lamps give out a great deal of heat and when placed as near the ceiling as would be necessary in the case in question the plaster and the supporting lathing would get more than warm. Woodwork subjected to continuous heat tends to become charred, or, at all events, to get into such a condition that it is ready to smoulder with very little extra heat, or if a spark should reach it from any flue. A couple of sheets of asbestos cloth attached to the ceiling with an air space of an inch or two will be a great safeguard.

Turning now for a moment to the question of groups, we are face to face with the greatest difficulty of all, and one which cannot be completely got over either in a daylight or artificial light studio of this size if a good effect of light and shade is desired on each face. In a daylight studio it would only be possible to light evenly a group of twelve figures by cutting down the side light to the minimum and employing a great deal of top and front light. Much the same course must be adopted with the electric light. The lamp must be brought nearer the camera or the figures on one side will get much more illumination than those on the other. In order to still further equalise the lighting over the whole of the group the same arrangement of reflectors as that suggested for groups of two or three sitting figures may be utilised, though the reflectors will need to be kept more nearly flat against the walls on account of the width of the group. The lighting will, of course, be rather flat, but under the conditions given this is inevitable.

Another method of getting a fairly uniform lighting, and a method, moreover, which will enable this to be done without altogether losing the normal character of studio lighting, is to keep the lamp in what may be termed the average position, that is, with the light a little above, a little to the side, and a little in front of the group, and then to interpose a tracing linen head-screen sufficiently large to diffuse the light over the whole of the subject. A second supplementary diffusing screen may then be used to cut off still more light from those four or five figures nearest to the lamp.

Some workers may prefer to effect a compromise by disregarding to some extent the unequal illumination, endeavouring first of all to so arrange the figures that the lighter draperies shall be farthest away from the light, then taking care to give a sufficient exposure to secure detail in the shadows of the figures most remote, and finally, shading the negative during printing, so that one side is not lighter than the other. With due care in the arrangement of the light on the lines suggested, if one half of the negative is a little thicker this will be all, and there should be little or no difference in the gradation and relative tones, so that extra printing will generally put matters right as far as the final picture is concerned.

It may be well to point out that the suggestions offered are merely a broad guide, and that in every room or studio an installation requires individual adjustment so that the distribution of the light is the most suitable for that particular apartment.

## MEASURING AND SURVEYING BY PHOTOGRAPHY

PHOTOGRAPHY is now a good deal employed as an aid in land surveying and map delineation, the fullness and accuracy of a photographic record taken with proper precautions from a given standpoint being quite above suspicion, and obtained much more quickly than by any other method. A few remarks on the principles underlying such work and the manner in which it is generally carried out may not be without interest. Occasions frequently arise when the photographer would be glad to know the precise measurements and other data connected with objects or places shown in his prints, and it is the intention of the present article to explain the very simple rules by which such facts may be deduced, even from a photograph taken in the usual way, without special apparatus. The legal value of photographic prints from which the dimensions and distances of buildings, which perhaps have been destroyed, can be proved with mathematical certainty need hardly be pointed out, and a knowledge of what can be satisfactorily demonstrated in this direction, merely from a single print, certainly seems among those things which the enterprising photographer might wisely make himself at least superficially acquainted with.

It will perhaps be best to commence by explaining a few of the geometrical and optical facts and formulæ which are of most use in this connection.

### Finding Height of Distant Object.

This problem depends upon four factors, any three of which being known, the fourth can at once be calculated. Thus, let  $O$  = height of object;  $I$  = height of image on ground glass, negative, or print;  $F$  = actual focus of lens (i.e., distance from optical centre to ground glass at time of taking photograph); and  $D$  = distance from object to optical centre of lens. Then

$$\frac{ID}{O} = \frac{F}{I} \quad (\text{See Fig. 1.})$$

That is to say, in order to make this clear to the non-mathematical reader, the height of the image multiplied by the distance of the object and the product divided by the (actual) focus of the lens will give the real height of the object. This formula can, of course, be used to find width measurements as well as heights, but in that case the result will not be accurate unless the plane of the object on which the width is measured is parallel to the focussing screen. In all these examples it is assumed that the camera is truly level and the plane of the focussing screen absolutely vertical.

### Ascertaining Distance of Object from Camera.

It has already been stated that, given three of the before-mentioned factors, the fourth is readily found. It follows from the preceding problem, therefore, using the same lettering, that

$$D = \frac{OF}{I}$$

or, in other words, if the measurement of the object is multiplied by the actual focus and the product divided by the measurement of the image, this will give the distance of the object. The actual focus of the lens may be deduced from the facts supplied by a photograph taken with it, providing the distance of any object is known, the formula being

$$F = \frac{DI}{O}$$

All objects whose bases are on a line drawn parallel to the horizon line of the picture are obviously at the same distance from the camera. Thus, in Fig. 2, it will be noticed that the base of the factory chimney starts from a horizontal line  $AB$ , parallel to the horizon line  $HL$ , and that this line  $AB$  happens also to cut the base of the lamp-post  $C$ . The latter, therefore, is at the same distance from the camera as the rear angle  $DE$  of the factory, and the height of the lamp-post, being

easily found, may be used to ascertain that of the line D E, or any part of it. In a similar manner, employing those factors which we know to find those which are not known, and, when found, using the latter to obtain fresh data, quite a remarkable amount of information can be scientifically built up from any reasonably clear photograph.

### Finding Horizon Line.

The horizon line of a photograph corresponds with that of the draughtsman, but with the obvious difference that in the present case it is fixed by the position of the lens instead of the observer's eye. To carry the resemblance further, all

Fig. 1.

retiring horizontal lines in the photograph have their vanishing point upon the horizon line, and all retiring horizontal lines which are parallel with each other have the same vanishing point. Furthermore, when these retiring horizontal lines are at right angles to the plane of the focussing screen their vanishing point will lie at the end of a perpendicular drawn from the plane of the focussing screen through the optical centre of the lens.

From the preceding facts it follows that, providing there are at least a couple of converging horizontal lines in a photo-

Fig. 2.

graphic print—the opposite kerb lines of a pavement or masonry courses in a building, for example—it is possible by producing these till they cut each other to find (a) the horizon line; (b) providing the said horizontal lines were at right angles to the plate, the exact point in the photograph which was opposite the lens centre; and (c), by a simple calculation, the height of the camera from the ground when the exposure was made.

As regards the latter, to find this produce any two converging horizontal lines on the print until they cut each other, and through the point of junction (vanishing point) draw the horizon line. Select any object in the picture which is known to rest on the ground level, and which cuts the horizon line—a lamp-post or flagstaff, for example. Suppose the lamp-post or other object selected is cut in half by the horizon line, as is nearly

the case with the lamp post C, in Fig. 2, then the height of the camera above the ground (or rather of the lens centre) is equal to half the actual height of the lamp-post, which may be either measured from the object itself or deduced by the formula  $O = \frac{ID}{F}$ , as previously explained. To state this more exactly:

The measurement on point of any vertical line starting from ground level to where it cuts the horizon line, multiplied by the distance of said vertical line from camera, and the product divided by the actual focus of the lens, will give height of camera (lens centre) from ground. It is, of course, assumed that the ground is practically level, although it is quite possible to

Fig. 3.

allow for any regular rise or fall, if known, by adding this to, or subtracting from the result.

### Calculating Distances from Print.

When the horizon line can be deduced from a photograph, as described in the previous paragraph, and the actual focus of the lens is known or can be calculated, it is possible to ascertain the distances of any objects which appear in the print by using the following graphic method:—At one end of any ground line of indefinite length, G L (Fig. 3), erect a perpendicular, and mark off upon it a distance H L equal

Fig. 4.

to the height of the lens centre above the ground—of course, to some convenient scale. Through H draw a perpendicular H H, parallel to G L, and step off upon it a distance C H equal to the actual focus of the lens. Now, on the print, rule a line through the base of the object whose distance is to be ascertained parallel to the horizon line, and carefully measure the distance between these two lines. Next, reducing it to the same scale as is used in the diagram, mark off a similar distance A H in the latter, above the horizon line H H. From A through C draw a line cutting G L in D. The distance D L is then equal (read to scale) to that of the object shown in the photograph. The other lines in Fig. 3 show how a number of distances may be found in the same manner. It is obviously feasible, by means of a large diagram of this kind, and reversing the previous procedure, to construct a scale of distances applicable to any photograph taken with

a given lens focus and at a definite height from the ground, and a number of such scales may be calculated for different foci and heights. An adaptation of this method is seen in M. Bertillon's system of metric photography, in which various scales are used to give at once, when applied to a photograph, the distances and measurements of any object represented in it.

#### Measurement by Means of Two Photographs.

When it is possible to take two photographs with a measured distance between the respective standpoints, the dimensions and distance of any inaccessible object can be found by means of the following method:—The camera is set up in two successive positions, each in a line with the object, taking care to keep a central vertical line of the latter in the same position on the focussing screen on both occasions, and using the same lens focus throughout. The distance between the lens centres in the two positions (or, if preferred, the plane of the focussing screen) is measured, and may be called  $B$ . Then, if  $I_1$  and  $I_2$  = the heights of the two images,  $B$  = the actual focus of lens, and  $O$  = height of object,

$$O = \frac{B I_1 I_2}{F (I_2 - I_1)}$$

Or, to show this graphically, draw a line  $A C$  (Fig. 4), and from one end, to any convenient scale, drop a perpendicular  $I_1$  equal to the height of the image in the first position (that furthest from the object), and measure off on the horizontal line a distance  $C F_2$  equal to the lens focus. From  $F_2$  set off the distance  $F_2 F_1$  equal to  $B$ , the distance between the

Fig. 5.

two positions of the camera), and from  $F_1$  mark off the distance  $F_1 C_1$  equal to  $F_2 C$ . From  $C_1$  let fall a perpendicular  $I_2$  equal to the height of the image in the second position. From  $I_2$  through  $F_1$  and from  $I_1$  through  $F$  draw lines meeting in  $G$ , and from  $G$  let fall a perpendicular cutting  $A C$  in  $H$ . Then  $G H$  is the required height of object.

The height (or width) of the object having been found, the distance may be deduced by means of the method shown in Fig. 1, the formula being from the selected standpoint either

$$(a) D = \frac{OF}{I_1} \text{ or } (b) D = \frac{OF}{I_2}$$

#### Apparatus for Photographic Surveying.

In surveying by photography a rigid stand is essential. The camera should be provided at the back either with a sheet of plain glass ruled with a horizontal and a vertical line crossing in the centre, or with small metal points, one at each side. The ruled glass, coming just in front of the plate

during exposure, will register on the negative the exact position of the horizon line and of the lens centre, or the metal points will indicate in the print how pencil lines can be ruled to serve the same purpose. The crossing place of the lines on the ruled glass, or of those settled by the metal points, as the case may be, must be carefully adjusted to coincide with the centre of the lens, and the lens board and front should have guide marks, so as to render it possible to always secure that the lens is in this position. A graduated scale working against a zero mark on the camera front is advisable, in order that when it is really necessary to raise or lower the lens the amount of deviation from the central position may be noted for future reference. The ground glass should be cemented in the frame to prevent it shifting when making measurements by its aid. The best lens to use is a wide-angle rectilinear, and, to secure uniformity in calculating, this should always be employed at the infinity focus. Accurate levels are required on the camera, as well as a compass to give the direction in which the view is being taken. In specially made surveying cameras certain features of the theodolite are commonly embodied, as, for instance, a circular graduated scale over which the camera revolves, thus enabling the angle between successive views, or between different objects in the same view, to be readily recorded at the time. By this means, when the compass direction of the first exposure is taken, the direction of all the others can be found with a minimum of trouble. In the photo-theodolite designed by Mr. J. Bridges-Lee, M.A., mechanism is arranged inside the camera which automatically records on the negative, besides the horizontal and vertical guide lines, the magnetic bearing of the principal plane and a scale of angular distances right and left of the latter. There is also provision for recording, at the desire of the operator, any memoranda relating to the height of the station, barometric pressure, station number, number of photograph, date, time, etc. At the top of the camera is the theodolite telescope, and rigidly attached adjustable crop levels, which enable the apparatus to be expeditiously and exactly levelled.

#### Method Adopted in Surveying.

In surveying by photography, the work is accomplished by a system of triangulation from a carefully planned base or series of station points. A number of negatives are taken, in any convenient series, in such a manner that any given point to be projected in the plan is included in at least two different negatives from varying stations. It is indispensable that the camera should be accurately levelled and the plane of the focussing screen strictly vertical. The horizon line, also, should be constant throughout the series of pictures, or a very exact record of any variation kept. Each negative is numbered, and systematic notes of its position on the planned base and its compass direction are entered. Then, assuming that prints have been obtained from all the negatives, the principal points to be plotted are marked on the horizon line of each print by means of perpendiculars drawn from them to the horizon, and corresponding points in different prints are lettered with similar letters. On the plan of the base, with each station point as centre and the lens focus as radius, circles are drawn, and tangent to these circles lines to represent the plane of the respective negatives, taking care that each is given its proper compass direction. Of course, all this must be done to the same scale as the plan. The distances of the various marked points right and left of the vertical line in the different photographs are now measured and reproduced to scale on their respective tangents in the plan, lettering them to agree with the prints. Lines are then drawn from each of these transferred points on the tangents, through the centres of the corresponding circles, and where the lines representing the same letter or

object intersect a point may be plotted on the plan. By joining the respective intersections, the whole survey is eventually completed. This is illustrated by Fig. 5, in which A B is a measured base plotted on the plan, C and D station points, E F and G H tangents to circles drawn as described, and having the required points marked on them from their proper negatives. The manner in which the lines drawn from these points through the centres of the circles intersect and are used for plotting the required plan will be understood from the diagram.

#### Contraction or Expansion of Prints.

The liability of the paper print to expand or contract during toning or development, and the after manipulations, is naturally a matter of interest, since if serious it is likely to render the photographic record inaccurate. According to the experiments of E. J. Spitta ("Photography," November 28, 1905), prints on any ordinary paper support do not expand except when wet, while when dry a slight contraction takes place,

which in some cases is uniform in both width and length, and in others may be greater in one direction. The writer may, however, point out that this can only apply to unmounted prints, since it is within the experience of most photographers that prints do decidedly stretch in one direction when mounted, at any rate when the mountant is strong enough and the mount sufficiently stiff to prevent contraction in drying. Spitta found that, with some bromide papers, the contraction is quite prevented in one direction, and reduced to a negligible quantity in the other, by wetting the back of the paper and allowing to dry before exposing. This would seem to be a subject to which manufacturers might well devote their attention, with a view to the production of a non-expansive and non-contracting support. In the present state of affairs, it may be suggested that when absolute accuracy is required, all measurements should be made from the negative itself, or from a contact transparency on glass, since these have been found neither to expand nor contract.

A. LOCKETT.

## A NOTE ON THE REVERSAL OF SOLARISED NEGATIVES WITH FARMER'S REDUCER.

If a bromide negative is exposed under a photometer in such a way that the more transparent area of the fields appears already as a positive by solarisation, and the negative obtained by this is reduced afterwards with Farmer's reducer, then a part of the reversed (by solarisation) regions is changed again into a negative. This is best to be seen in those places where the solarisa-

fine grains which are to be seen in the lower parts of the film are much finer than those in the corresponding parts of the solarised portions. It is easy to understand that a reduction with ferricyanide of potassium under certain circumstances must invert the relative portions of transparency of these two parts. Suppose the reducer has penetrated down to the half of the two

Fig. 1.

Fig. 2.

tion has not gone too far. This phenomenon is easily explained by the microscopic examination of vertical sections of the films. Figs. 1 and 2 show such vertical sections. Fig. 1 is the less exposed, and Fig. 2 the solarised. It can be clearly seen that the less exposed parts must be much more opaque than the more exposed (solarised). In the solarised parts the grains are equal in size and evenly distributed over the whole thickness of the film. In the less exposed parts the size and quantity of grains in the upper parts are both greater. The comparatively few

films equally. In Fig. 1 the greater quantity of the grains has dissolved, and only a very slight opacity remains. In Fig. 2 comparatively more of the grain remains unattacked, and consequently the parts, formerly more opaque, must be relatively more transparent after reduction. These experiments naturally succeed well only if the plates are thoroughly developed with a well-penetrating developer of strong action. The fact that the solarised part is thinner is explained by the hardening of the film by solarisation.

DR. W. SCHEFFER.

**SALISBURY Camera Club.**—The second annual exhibition will be held on February 5, 6, and 7. There are to be four open classes, with Mr. S. G. Kimber as the judge. Enquiries and applications should be addressed to Mr. T. S. Bloom, Farnett, Salisbury.

**A LANTERN-SLIDE Competition** is announced in connection with the Northumberland and Durham Federation. Plaques will be awarded for the most pictorial slide. The judges are Messrs. Walter S. Corder and A. E. Cowling.

## BUSINESS ASPECTS OF PROOFS.

The following two contributions, which we quote from our American contemporary, the "St. Louis and Canadian Photographer," discuss certain of the points which are equally vexatious to the professional photographer in this country.

In taking up a subject of this kind, writes Mr. John A. Schreurs, it is the intention to endeavour to prove the commercial value and practicability of the plan of which this article treats. Many a dollar has eluded him, many resittings made needlessly and at his expense if the photographer has not thought that it pays to retouch, partially, his negatives before showing proofs. Enough is being said about every other branch of the profession. What of our knowledge in advertising, in the art of portraiture, in the skill necessary to the obtaining of a good order—does it not all depend, all the previous efforts hinge, upon how well pleased the sitter is at first sight of the proofs?

### Retouching for Proofs.

It is known that in nearly every studio there are negatives that are never ordered finished. It is also a fact that people will try to obtain a sitting without leaving a deposit—for the only reason that they want to see first how the proof will look. Then, with these facts before us, we ought to find a way to meet them. Retouching is done in most studios in one of three ways: by the piece in the studio or at the retoucher's home, on a salary at the studio, or by the proprietor. How can this necessary work be done in all the above instances? If the proprietor is a retoucher the best results can be accomplished if he does it himself: because, in most studios, he will make the sittings and will know from his conversation with the sitter what he or she wishes. If the retouching is done by a person on a salary their time will be well spent. If, as in the first instance, by the piece, a reasonable amount can be agreed upon. The piece workers might find that the number of negatives to be retouched had increased, after trying the plan, and could afford to do the necessary work free. It will be found that the reception room work will show better results, and three dozen from three or more styles will not be an uncommon order, where previously one dozen from one was the average. The amount usually charged for retouching extra negatives, cabinet size, is from fifty cents to one dollar. It is not for the gain of this extra amount alone that we speak but that the sitter will be better pleased with the proofs and will invariably give a larger order. With this in view, a pleased customer is willing to give a liberal order. The price for retouching extra negatives can be made less than regular, say two negatives for seventy-five cents; or, if figures, three for one dollar; in other words, don't let a too high price for retouching keep a customer from placing a good order. The way a proof is made, and shown, is of considerable importance. Too often any old kind of paper is made to do, and the colour and size given no consideration, just so it prints. But the experience of many is that the paper cannot be too good, nor should it be too small in size. In some studios a folder is used to contain proofs and in which to exhibit same, and no doubt many other neat ways are in use to help to make an impressive-looking proof.

In the retouching of the negatives for proofing all in the order need not be retouched. The vast difference in the ones so treated and those which you may choose to leave unretouched, will be an aid to you to influence the sitter to order from the ones which, in your judgment, you know will finish the best. Often the customer will want to order from a proof that is from an inferior negative, they not knowing that it is such, because it was printed light, or some similar reason, when it would not finish nearly as good as another. All proofs ought to be returned to the studio, and the fact emphasised by the printed request on back of the proofs.

### Proofs Unpaid For.

In these days of the numerous amateurs, many an extra negative failed to get an order owing to the fact that it has been fixed and made to answer as an extra "photo" from your studio, and you are out the fifty cents or more which should have come to you. And, in addition to that, the sitter is more likely to want the extra styles if they are not allowed to keep the extra proofs. In some instances it might be advisable to let a sitter keep a proof for a certain length of time, if it was one particularly liked; but the photographer should make a memorandum of the fact and, when the time arrives, write a request for an order. Much could be written in regard to the necessary changes to be made in improving a negative before proofing, but that would require too much space and needs a separate treatise. In some instances the mere softening of a line, or the removal of a facial defect, or the changing of the outline of a figure, will satisfy the person, but care must be taken not to go to extremes. The proofs are usually seen by members of the sitter's family, and frequently numerous friends are asked to pass judgment; some flattery is permissible and will be recognised to your credit, but do not let the friends have cause to say: "How changed from what he once was" (*Quantum mutatus ab illo*).

Amateur photography has come to stay and its enthusiasts are to be found in nearly every home. No doubt your customer has had a "picture taken" at home in the easy attitude thought to prove just right, because natural and in a congenial environment, and has decided to try the photographer. Think you they will be looking for a fuzzytype, or want to look too natural? No, they have been experimented upon, have seen themselves in the easy attitude, and are expecting to see, even in the proofs, that they are not so uncommonly homely after all. It is the sitter who is enthusiastic about the proofs, who is really agreeably surprised, from whom the large orders are obtained, providing they are well pleased with the proofs. It is true there will need to be some talking done in the reception room, but if the person is pleased at the start the large orders are all the more readily obtained.

### A Uniform Charge for Each Unreturned Proof.

In regard to the return of all proofs, and where the same have not been returned, instances like the following have been known to occur: A sitting of an attractive child was made on the understanding that if the proofs were good a combination was wanted. Ten or twelve fine proofs were sent to the mother, and a deposit of \$1.50 had been made on the order. Some time afterwards the photographer was asked if he had made all those fine pictures for Mrs. B., and much to his surprise he learned that the proofs had been "fixed" and framed into a combination photograph. Children's photographs do not need much retouching, and they, more often than those of older people, are kept when they should all be returned. Well, the proofs had to be returned to the studio where this incident occurred, or paid for, after the facts were discovered. A price of 25 cents is demanded for each proof not returned in some studios when persons retain same after request is made to "return all proofs." It is true the above instance has more to do with the return of proofs than the retouching of same, but it shows the need of giving more attention to them.

In conclusion, I think that the proof has a good deal to do with the amount the photographer will realise from each sitting.

Among the numerous ways now in use in the better studios to obtain orders for higher-priced work, when the customer does not seem disposed to order the best, is to make other negatives than the size ordered, and when the proofs are seen finished, platinum prints of the special ones are also presented for approval, which usually brings the desired result. But will not, after all, an order for two or four dozen photographs from four to six different negatives pay the photographer more and be a better advertisement for him than one or two specially finished ones only to be seen in one or two homes?

### A Business Practice.

I am inclined to think (writes R. W. Phillips) that the profession as a whole are thinking a little too much of their work as being strictly in the line of a business. While business methods are undoubtedly necessary, there is one thing which must not be forgotten, and that is that we are closely allied to the Arts. Whether times are dull or profitable the conscientious photographer should adopt this universal rule, "Never allow a client to receive unsatisfactory pictures, no matter what the cost."

This, it seems to me, covers an immense field, and could be talked on for hours at a time. One can readily see the great harm that may come to future business by having adverse criticism. One customer may influence from ten to five hundred dollars' worth of business, and the harm done by an adverse critic will travel and cover twice as much ground as the successful word. The impression made by a neat enclosure for carefully made and occasionally partly retouched proofs, undoubtedly has its effects upon the customer. After many trials, we now use this method:—

We have proofs, made and cut in uniform sizes, and enclosed in a neat folder, of a colour harmonious to the paper used for the proofs. They are placed *one over the other*, and held in place at the top by the use of a Hotchkiss No. 1 fastener. Separate proofs are then not laid in the light to fade during inspection by others. A favourable impression caused by any one proof or proofs may thus be rendered more complete by this temporary isolation. We print on our folders an explanation of what the proofs mean, and that they must all be returned, or a charge made as for finished pictures. Since the adoption of this policy, we have found that our customers invariably return them all.

## FOREIGN NOTES AND NEWS.

### Acid Diamidophenol Developer for Lantern Slides.

A committee of the Société Française has recommended the award of a bronze medal to M. Balagny for his method of obtaining warm tones on chloride or chloro-bromide lantern plates with an acid diamidophenol developer. The plates used were Ilford Alpha and Edwards' chloride, the exposure for the former being 3 cm. of magnesium ribbon et 10, 20, and 30 cm. respectively, whilst for the latter plates 4 cm. of magnesium were used. The developer was:

Diamidophenol .....	2.5 gms.
Bisulphite solution .....	40-50 ccs.
Ammonium bromide, 10 per cent. sol. ....	50 ccs.
Sodium bisulphite lye .....	25 ccs.
Water, to .....	1000 ccs.
The bisulphite solution above referred to is composed of:	
Water .....	125 ccs.
Sodium sulphite anhydrous .....	20 gms.

Dissolve and add:

Sodium bisulphite lye .....	75 ccs.
The image first appears of a maroon colour, and as development proceeds changes to sepia, and the whites keep absolutely clean. As soon as the desired colour is obtained the plate should be well rinsed and fixed in:	

Hypo .....	250 gms.
Sodium bisulphite lye .....	20 ccs.
Water .....	1000 ccs.

and then washed as usual. The committee state that the transparency of the whites is perfect, and that there is no blocking up of the shadows.

### Formation of the Silver Halides in Jelly.

Dr. Lüppo-Cramer describes, in the "Photographische Korrespondenz," some experiments on this subject. Plates were coated with a 10 per cent. solution of gelatine containing  $2\frac{1}{2}$  per cent. of potassium iodide, or the equivalent quantities of bromide and chloride. A few drops of a 10 per cent. solution of silver nitrate were dropped on the plates, and it was seen that the iodide became cloudy first, then the chloride, and finally the bromide, the two latter merely causing a fine opalescence. If a solution of ammonio-nitrate of silver was used, opaque films were immediately obtained, and the iodide was the slowest in formation. Ammonia thus acts directly on the formation of the opaque halides and acts as an energetic ripener, when the latter are *in statu nascendi*. Opalescent films bathed in ammonia also became opaque, but only slowly ripened. Silver chloride ripens more quickly at first, but is then caught up by

the bromide and surpassed. Silver bromide exposed under a solution of silver nitrate darkens more rapidly than the chloride, but is caught up and surpassed by the latter. When a gelatine-potassium-bromide plate, containing 1.5 (bromide) of iodide was bathed in silver nitrate the film became much more opaque and more yellow than the pure iodide. The rapidity of the formation of the halide in this case is not more rapid than with pure bromide, but the mixture is at once more yellow, and this colour is much more striking when ammonio-nitrate of silver is used.

### A New Panoramic Camera.

Commander A. Daubresse has invented a new panoramic camera which embraces the whole horizon, or 360 deg. It is constructed by the well-known optical house Krauss, of Paris, and is shown in figs. 1 and 2, the latter giving the exterior view of the camera, in which a film is used with spools in the usual manner. Fig. 1 shows the optical part, and it will be seen to consist of two rectangular prisms between which is placed the lens, with its axis vertical.

Fig. 1.

Fig. 2.

If the image  $N_1$  is constructed from the nodal point of incidence  $N_1$  of the upper prism, and also  $N_2$  from the nodal point of emergence  $N_2$  of the lower prism, it will be at once seen that the points  $N_1$ ,  $N_2$  play the same part as the nodal points of a lens used alone, namely, that an incident ray, passing through  $N_1$ , gives rise, after traversing the system, to an emergent ray parallel to the first, and passing through  $N_2$ . The principle pointed out by M. Moëssard should then be applicable to this optical system.

and if the whole collection of lens and prisms is revolved on a vertical axis XX passing through  $N_2$ , the image of an exterior point should be immovable on the film.

### The Action of Hypo in the Ferrous Oxalate Developer.

Dr. Lüppo-Cramer has been investigating the accelerating action of small additions of hypo to the ferrous oxalate developer. The presence of sulphite in the developer prevents the solution of any silver bromide by the hypo, and also prevents the formation of silver sulphide; but if the hypo is used as a preliminary bath the sulphite has no restraining action. The author finds that ferrous oxalate reduces the silver bromide dissolved in the hypo much more rapidly than an organic developer. He confirms Gaedick's statement that a mixture of equal molecules of silver bromide and hypo does not form the theoretical salt, but that some of the silver bromide is always dissolved, and that some remains as a precipitate. This residue was not found to be pure silver bromide, but a compound of bromide and hypo, which was decomposed by washing, and always gave a filtrate that became cloudy. When heated with nitric acid this compound gave silver sulphide. It is thus clear that small quantities of hypo combine

with some silver bromide, and this compound is much more easily reduced by ferrous oxalate than silver bromide. Therefore the initial rapidity of the process of development is increased by the addition of small quantities of hypo.

### A Test for Gelatine.

When a solution of gelatine is vigorously shaken with benzine (petroleum spirit), some of the colloid is precipitated as a stiff emulsion of gelatine, benzene, water, and air. With very dilute solutions the result is a permanent whitish ring of exceedingly small bubbles, settling around the walls of the vessel. This reaction is very delicate, serving to detect a few mgrms. of gelatine per litre. It is best carried out with quantities of 10 c.c., in a vessel of the diameter of an ordinary test-tube. Slight acidity of the solution is favourable, but in presence of much acid, alkali, or salt, the test must be performed on larger quantities. It is found that petroleum, melted paraffin, benzene, chloroform, and carbon bisulphide may also be used. Solutions of other colloids, both organic and inorganic, give the reaction. Tannin reacts, but gallic acid does not. Conversely, solutions of fats in hydrocarbons give similar permanent layers of emulsion with water, or (better) dilute alkaline or acid liquids.—A. Winkelblech, in "Zeitschrift für Angewandte Chemie," through "Journ. Soc. Chem. Indus."

## A NEW METHOD OF MEASURING THE TIMES AND EFFICIENCIES OF PHOTOGRAPHIC SHUTTERS.

(Continued.)

THE reading of Mr. J. de Graaf Hunter's paper, reported in our last two issues, was followed by a discussion on the report, which we publish, by courtesy of the official organ of the Optical Society, the "Optician."

Sir William Abney said the apparatus they had had the advantage of seeing before the paper was read, was very beautiful in design, and, so far as his knowledge went, was novel. It seemed to him to have been worked out with very great skill and care, and he was surprised at its accuracy and the small difference there was in the two or three readings in succession. He was glad that Mr. Hunter had called attention to the actual times and the nominal times, as no one knew, perhaps, better than he, that the ratios of the times put on shutters were in many cases absolutely fictitious. As a rule, the speeds merely indicated that the plate was exposed for a longer or shorter time, and that nobody who knew this would ever think of using the figures marked on the shutters. That, at any rate, was his experience—he would mention no shutters and no names, but there were a great many sinners in that respect, but he had not the slightest doubt that they arrived at their figures by some means or another.

If they got one of the instruments now shown they would, at all events, have the correct nominal exposures to go by. A good deal of experimental work had been carried out by amateurs in measurements in which they had taken for gospel the makers' times of exposure. This was unfortunate, as it rendered such work of but little use. Of course, one had to recollect that with shutters the actual exposures might vary, for anybody who had used a shutter in which thin plates of ebonite formed a part would know that the exposures varied very considerably.

### Causes of Time Difference.

There was one shutter he had in mind with regard to which he could say the times had varied between 1/100th of a second and about 1/12th of a second, though they were supposed to be the same. The difference was due to change of temperature and deposit of moisture. So that one must not blame the makers altogether. He would not make further observations except to congratulate Mr. Hunter on the very efficient apparatus he had introduced, and he hoped it would be found useful to the manufacturers of different kinds of shutters.

Mr. Conrad Beck said that some years ago he noticed that a certain shutter put on a certain camera was marked 1/100th, which a year before had been marked 1/50th, and without any very apparent change, the next year it was marked 1/150th. He was bound to say that he wondered where it was going to stop. At that time he com-

menced a scheme by which he tried customers' shutters for 4d. each, and he tested nearly 6,000.

In the course of this work they got some extremely interesting information. He certainly could endorse everything Mr. Hunter had said as to the question of accuracy of speeds; at the same time he was bound to say there were many ways of looking at it. For instance, if a shutter opened from the centre and closed to the centre, the exposure which was required to be given according to exposure tables, would not be in the same ratio to the total time the shutter was open as that required by a focal plane shutter. Consequently, there were two methods of defining the rapidity of a shutter, one of which had reference to the amount of light admitted into the camera, and regulated the exposure necessary; the other had reference to the period during which a hand camera could be held steady, and to the movement of a quick moving object being photographed, and he thought there was some difficulty in expressing the speeds of shutters for that reason.

### Size of Aperture.

It was the simplest, and perhaps the more practical and certain method of expression, to state the actual period which the shutter opened the central portion of the lens. If the total time during which a shutter was open, modified by an efficiency co-efficient, were taken as the speed of a shutter this might be quite incorrect, because the shutter might have a full aperture of 1-inch on which the efficiency was calculated, whereas the lens used with it had perhaps an aperture of  $\frac{3}{8}$ -inch.

Then, again, one had also to consider the size of stop or aperture of the lens which was going to be used. If he might be allowed, he would indicate a few points on the blackboard. Mr. Hunter had been suggesting that his method was a fair test of a blind shutter, but it was not true to take the total motion of the blind. (Mr. Beck proceeded to sketch a diagram on the blackboard.) A blind shutter working in front of the lens commenced by exposing one edge of the plate, the rest being in darkness; and this edge of the plate ceased to be illuminated some time before the shutter had completed its travel. Thus, a measurement giving the total travel of the blind did not give a correct measurement of the exposure at any one point of the photograph, and was not a useful mode of expressing the speed of that shutter. He merely raised those points with a view to showing that the question of expressing speed of shutters ought to be carefully discussed and set forth by some consulting body who

would consider all these points, in order that some systematic method could be adopted. He thought there were two distinct points which every man wanted to know. Firstly, the speed of his shutter with reference to exposure. Secondly, how much the moving body would move during the exposure, and the probability of shaking the camera during the exposure. They were extremely difficult points, and it was very difficult to know what was the most convenient method of expressing the speed when two such dissimilar points had to be considered.

He thought Mr. Hunter was to be congratulated on his method of testing shutters—the change of speed and other details were ingeniously worked out. He must say he should feel a great deal of satisfaction if, as a check to some of Mr. Hunter's results, they had one or two photographic tests—for instance, Sir William Abney's method—to test their accuracy. In starting any method it was above all essential that there were no sorts of errors creeping in. He was bound to say, judging from the average of his own results, he was a little suspicious as to whether Mr. Hunter's figures did not give shorter exposures than should be the case. In a method he had himself adopted for testing shutters, which had to be a rapid method, the shutter was placed before the eye, a small stop being used and a series of bright spots rapidly uncovered by a revolving slit was observed.

Mr. Hunter's machine was a modification of the invention of Mr. Kershaw, of Leeds, which he thought was the most ingenious he had ever seen. That method was patented by Mr. Kershaw four or five years ago, and he used it for testing his focal plane shutters. For that purpose he did not think it could be much improved, and in discussing a question of this kind he thought credit should be given to Mr. Kershaw for his method. He would like to hear whether Mr. Hunter had any photographic confirmation with reference to the results of his individual tests mentioned in his paper, because it occurred to him—although perhaps he had no right to say so without actual experiment—that some of the speeds appeared to come out a little high.

#### Sir William Abney on "Time of Duration."

Sir William Abney wished to add one or two words in reference to the time of duration in the method he adopted himself—the photographic method. Of course, he always used the method with the lens which was going to be used—not without a lens, although it could be measured without a lens—the photographic diagram had no possible meaning unless it gave the mean time of the exposure on the shutter with a certain stop. With the diagram method there was none of that uncertainty which Mr. Beck referred to. There was the time before them, and they could calculate it as they liked. (Here Sir William Abney drew a diagram on the blackboard.) With a focal plane shutter one could not judge of the ordinary rules of shutters, because they had only got to alter the slit, and they got as rapid an exposure of a certain portion of the plate as they liked. But where they had the shutters near the lens, the diagrams they got by the photographic method left no manner of doubt as to the speed obtained. Mr. Hunter had got approximately the total time a shutter was opened. He did not get the mean time, but he got his diagrams in a different way.

Mr. Purser said it would be a good thing if the speed of shutters could be accurately measured by such an instrument as that which Mr. Hunter had devised, but the question of more importance was the production of a shutter that would do credit to the measuring instrument. Manufacturers are quite conscious of the fact that the speeds of shutters are only approximately correct, and the production of an elaborate instrument for testing does not bring us any nearer the perfect shutter. In the production of such an article there are so many factors that affect the constancy of the working parts, such as changes of temperature acting on the springs of the shutter blades, grit or moisture on the valves, etc.; that, in the absence of constancy, it was not much satisfaction for the photographer to know that some time in a dim and distant past his shutter had worked at correct speeds, because at the present time, under changed conditions, it was working quite differently.

In recording incidents referring to the inconstancy in the working of shutters and other factors, Mr. Purser humorously asked the question, "Did we want speeds in shutters, and are they of any

use when we have got them?" He recently saw some photographs taken by a camera having a shutter working at nominal speeds of 1 to 1/100th of a second. They were hunting pictures, with horses and dogs scampering across a field, and the photographer recorded the information that they were taken at 1/25th of a second. It was generally considered by the amateur photographer that in order to take pictures of animals moving at a rapid rate across a field of vision a speed of at least 1/300th of a second was necessary. He also remembered conversing with a gentleman who had promised to lecture at a local photographic society on "Exposures," and "Rapid v. Slow Plates."

Just two days previous to the lecture he purchased a packet each of extra rapid and ordinary plates, and made a few exposures. On developing the plates under the same conditions he found precisely the same results, the negatives from the extra rapid plates being quite indistinguishable from those of the ordinary plates, notwithstanding the fact that the exposure given had been precisely the same. Whether this result was due to lack of constancy in the working of the shutter or to other causes is not recorded, but the incident goes to prove that where so many factors are unreliable it must be difficult to arrive at satisfactory results, and he thought that an elaborate method of testing of shutters could not be of any serious service to amateur photographers until such time as a shutter could be produced that would give constantly reliable speeds.

Mr. Rosenhain said he particularly admired the ingenious mechanical arrangements of Mr. Hunter's apparatus, and especially the change-speed gear; he only wished it were possible to apply such a form of gear to the transmission of a considerable amount of power, but he understood from Mr. Hunter that there were very serious obstacles to its use, so that those who had looked at the gear and dreamt of noiseless motor cars should not be too sanguine. In the mechanism for releasing the shutter at the proper moment there seemed to him a slight duplication; could not the electro-magnet used to put the mechanism into action be employed to cause the release of the shutter directly?

Further, after looking at the very perfect arrangements of the apparatus, he (Mr. Rosenhain) was led to wonder that no greater degree of accuracy than that claimed by Mr. Hunter (20 per cent.) could be attained; on looking through the figures given in the paper, in fact, it appeared as though Mr. Hunter's claim were rather too modest. He supposed that the object would hardly justify such a refinement, but by the use of a chronograph, the speed of rotation of the disc, at all events, could be measured to a much higher degree of accuracy than the 6 per cent. mentioned in the paper. However, while he (Mr. Rosenhain) was thus asking for greater accuracy, others had said that no speed-testing of shutters was required at all—that these measurements were of no real value to the users of shutters. He did not at all agree with that; if he knew what certain shutters did under standard conditions, and how far they were liable to vary, that would be a means of discriminating between the good shutters and the bad, and would thus be the first step towards the attainment of the perfect shutter.

Even Mr. Hunter's results, as they stood, appeared to show that the roller-blind type of shutter was less liable to vary than the diaphragm shutters. As for the argument deduced from the fact that with the same exposure equally good results might be obtained upon fast and slow plates, that hardly bore on the question; they all knew that by suitable development good results could be obtained with enormous variations of exposure, but for that purpose it was desirable to know approximately what the exposure had been. Similarly as regards a hunting picture taken with an apparently abnormally long exposure, everything depended upon the point of view relatively to the motion of the animals; under unfavourable conditions in this respect a sharp result could sometimes be obtained with relatively long exposures by a suitable movement of the camera during exposure. In any case, the first step towards scientific accuracy in photography was to have the means of knowing the actual duration of the exposure given in any particular case, and he thought they all felt that Mr. Hunter's apparatus would be of considerable service in that direction.

#### The Rate of Opening of Shutter.

Mr. Horace Beck said that there was one question raised by Mr. Rosenhain on which he would like to say a word or two, namely, as

to follow an object by swinging the camera. He had found this a most satisfactory method, and by doing so he had taken photographs at an actual speed of about  $1/100$ th of a second of tobogganing on some of the ice runs, whereas by keeping the camera steady he required  $1/500$ th of a second to get equal sharpness of the moving object. In this case he had a specially speeded up shutter for the experiment.

Another point which arises is, that if one is taking the total length of exposure in the method which Mr. Hunter is using, one takes it from the time the lens begins to uncover, and goes on to the time it is completely closed. In many shutters the rate of opening is a comparatively gradual one at starting, and it then opens more rapidly to a maximum, closing again more rapidly at first, and then more gradually. This applies particularly to any shutter in which a circular aperture is opened by means of straight-edged plate. Thus, only a very small amount of light enters the camera at the time the shutter is beginning opening and finishing closing.

Supposing that in a correctly timed exposure the first and last  $1/10$ th of the exposure do not give sufficient light to appreciably affect the plate. It can be calculated that in some shutters which, taken in Mr. Hunter's method, would show a certain speed, in actual practice would give results of 50 per cent. difference as far as movement of the object goes.

Another reason why one wanted correct speeds for photography was that when one was using a slow speed a person who had a good, steady hand, could hold a camera comparatively steady for a tenth of a second, and occasionally for longer, but with the ordinary person it was perfectly certain, in the vast majority of cases, that if he had a shutter which, when set at the nominal  $1/25$ th of a second, was really running at a third of a second, he could not help shaking the picture. Then, with reference to Mr. Hunter's actual instrument for testing, he thought it was an extremely ingenious arrangement, particularly the device of the rubber ball between the two cones.

He believed if Mr. Hunter wanted to apply it to greater power he could do so by putting a solid bicycle tyre in between, which would hang loosely on one cone. Then Mr. Purser raised another point, namely, the difference that occurred either by accident or malicious intent, owing to foreign matters getting into the shutters. Many of the shutters his firm had received for repairs were in such a condition that they reminded him of the "Mad Hatter's" watch in "Alice in Wonderland," who, when he complained of the treatment it had received, the March Hare replied, "But it was the best butter."

#### Dr. Drysdale and Stroboscopy.

Mr. Chalmers said he was very much interested in Mr. Hunter's paper. As an easy means of measuring the speed of the disc and determining its constancy, the method described by Dr. Drysdale, in his paper on "Stroboscopy," read to the Optical Society some time back, might be useful. Mr. Hunter had encountered difficulties due to the necessity of setting on the two ends of a scale; a similar difficulty occurs in the "ophthalmometer," and is there obviated by the device of "doubling the image." This device would render the method independent of the constancy of the shutter, and thus enable it to be applied to test this constancy.

He thought that the ideal method of testing shutters would be one which gave an actual picture of the shutter at regular intervals during exposure. He therefore suggested the use of a photographic recording drum, on which images of the shutter were focussed by the aid of a good lens. If the shutter were illuminated by intermittent light, pictures of the shutter at regular intervals could be obtained. As a preliminary test of the method he proposed using an alternate current arc with a period of  $1/100$ th second.

He anticipated no serious difficulties for low speeds, but expected that it would be necessary to use a tuning fork to obtain the required frequency for high speed shutters. This method should give the efficiency and time of the shutter for any aperture, and should be specially applicable to roller blind and focal plane shutters. The suggestion of Mr. Beck that not only the actual time of exposure, but also its value for use with exposure tables, should be given, was most valuable.

Mr. H. S. Ryland congratulated Mr. Hunter on his method of

attacking a difficult problem. The chief source of inaccuracies appeared to him to be that the speed of the disc was not constant. This could be eliminated by a self-recording centrifugal speed indicator. Then the speed could be easily read at any moment, or a key could be arranged, so that when depressed (as it would be at the instant of taking a reading) it would make the speed indicator band. In regard to the speed changing device, Mr. Hunter would deserve congratulation if his device were to lead to a decently quiet changing gear for our motor buses.

As to the need for a means of marking shutter speeds, that undoubtedly existed; but it was annoying when one had a shutter and could not tell the difference between 1 second and  $1/50$ th of a second. With such delicate mechanism as they had in shutters, it would almost be impossible to keep the speeds constant, but one did expect the ratios between the various marked speeds to be constant. The shutters should, he thought, be graduated for total time it is open, and its efficiency given at the aperture for which it was marked.

The President observed that, except in gathering up the threads of the discussion, he did not think he had anything to say before Mr. Hunter replied to the specific points raised. There was one thing borne in on his mind, namely, that in this matter they had one which should be considered by the Optical Standards Committee, as they had ample scope. He thought, however, that they had an agreement at the moment by which they had arranged that they would not interfere with photographic standards. Whoever undertook the work would find there were a great many controversial points, through all the intermediate stages, until they could decide on a standard nomenclature, and the degree of accuracy with which the numerical interpretation could be obtained and recorded.

#### Mr. Hunter's Reply.

Mr. Hunter, in reply to the various questions, said as to what was the proper time to engrave on a shutter, it seemed to him there was little doubt that it was the time for which an image of outside objects was formed by a lens, when the shutter was put close up to the lens, and released. One time which was of importance was the extreme time for which the photographic plate was exposed to light, which was the time during which an image was formed. To know the exposure, of course, it was necessary also to find the efficiency of the shutter. But what he called the time of the shutter gave correct information as to how far the position of a moving object would change during the time the shutter was open.

Of course, before knowing the performance of a shutter it was necessary to find the efficiency. From readings taken with apparatus described it was possible to plot an efficiency curve which gave the state of the shutter at any instant between its opening and closing. This curve was virtually the same as those given by Sir William Abney's method, and the method of finding points on the curve was applicable to all forms of shutter.

With regard to Mr. Conrad Beck's remarks, he (Mr. Hunter) had seen Mr. Kershaw's patent. The apparatus described in it seemed so different from his (Mr. Hunter's) own that he had made no reference to it. As far as he remembered, in this arrangement the shutter was held close to the eye, and a light was observed through the shutter and the radial slots of a disc. No image was formed or used as in the arrangement described that evening. As previously pointed out, the method was applicable only to periods shorter than that of persistence of impression on the retina. His (Mr. Hunter's) method and apparatus may be used in conjunction with a camera to make a photographic test. If it was considered that the visual method was in need of checking this could be done. A visual method, however, was considered more suitable on two accounts: (1) that it could be more rapidly carried out, and (2) that difficulties of getting sufficiently strong illumination would not occur.

#### Greater Accuracy of Measurement.

It had been suggested that speeds in shutters were scarcely any use, and that a shutter was bound to vary widely in performance from day to day, owing to wear, or dirt getting on the moving parts. If this was so it would be better not to mark times on the shutter at all. It was no use saying a shutter gave a hundredth of a second if it really gave a tenth of a second. He (Mr. Hunter) had heard of

the use of a rubber tyre between two cones, mentioned by Mr. Horace Beck, for a speed change mechanism. But to his mind it had not the same advantages as the mechanism with rubber ball between two cones. In this case the normal reaction required to give sufficient friction was automatically supplied, while in the bicycle tyre method it had to be specially applied. Greater accuracy of measuring the speed of the disc of the apparatus might be useful, and for this purpose a stroboscopic method would, doubtless, be very satisfactory; or, possibly, the continuous speed recorder suggested by Mr. Ryland.

The President said Mr. Hunter's suggestion that it might be desirable not to put speeds on the shutters, reminded him of a hydrometer, which not so long ago was used by the Inland Revenue for measuring the density of excisable liquids. Certain weights were issued with the instrument to correct for varying temperatures. These were marked "cold," "very cold," "warm," "warmish," "hot," "very hot," etc. In the same way the speeds of shutters might, perhaps, read "dead slow," "slow," "slowish," "quick," "quicker," "quickish," and so on, thus relieving the maker of the trouble of an exact numerical specification. In conclusion, he had a very pleasant duty to perform, namely, to ask them to accord their hearty thanks to Mr. Hunter for his paper.

### RELIEF-EFFECT PRINTS.

In the current number of the "Photo-Era" appears a contribution from Dr. Detlefsen on the making of prints with the effect of cameo relief, which may interest those of our readers with a taste for experimenting in new forms of photography. The method of Dr. Detlefsen is on the lines of that described by Mr. J. W. Gordon before the Camera Club some year or two ago. We referred to it in a recent issue on publishing a patent for substantially the same process. There are no difficulties in the process other than those of manipulation, and the print obtainable might well be applied by a professional photographer to the creation of a certain amount of interest among his customers in the method of their production. Dr. Detlefsen's notes run as follows:—

Cameo relief prints, so-called, may be produced successfully in two ways, briefly outlined herewith. The first method which I employed and published in the "American Annual of Photography" for 1906 is as follows:—From the negative to be used first print a positive on platinotype paper. Use a developer containing acetate of potassium and mercury, the addition of which produces great contrast—bright high lights and dark shadows. The developer is as follows:—

Acetate of potassium ..... ½ oz.  
Citric acid ..... 2 oz.  
Phosphate of potassium ..... ½ oz.

Dissolve in warm water and add:

Bichloride of mercury ..... 50 gr.  
(Previously dissolved in boiling water)

Add enough water to make one pint and use cold.

Now put a clear glass plate into the printing-frame, and on this place the platinotype print which you have just made, "face out." On this lay the negative, "face in," so that print and negative are slightly "out of register." Next place a sheet of platinotype paper on the negative, film to film; close the printing-frame, and print carefully. Expose to direct sunlight, if possible, and print from one to three days, until a fair outline appears. Print less strongly than for ordinary platinotype printing. Develop in acetate of potash and mercury developer.

The second method, employed by me since with results equally as good, is this:—Place paper positive on negative slightly out of register. Next put a sheet of platinotype paper on top of paper positive and close printing-frame carefully. Print and develop.

**CINEMATOGRAPHY in Colours.**—Daily exhibitions are being given by Mr. W. Friese-Greené of cinematographic projection in colours at the studio of the "Natural Photograph" Company, 203A, Western Road, Brighton. The company offers to make photographs in natural colours for customers by the three-film superposition process. The price is ten guineas for one picture.

### PENCIL PHOTOGRAPHS.

THE latest craze in Paris is the beautiful "pencil photo," writes the correspondent of the "Tribune." These lovely and exceedingly costly portraits were introduced at the beginning of the present season by a clever young artist from Vienna, and now they are all the rage. The pictures—which are never large—look exactly like fine pencil sketches, but they are actual photographs. The process is kept a secret, but I have come to the conclusion that in the first instance a partial enlargement is made from an ordinary photograph, and then the details are filled in with a finely pointed pencil. After the picture is finished in this way it is photographed on a small plate, the prints then being taken in a specially soft manner.

The "pencil photos" executed by the artist to whom I have alluded are only for those fortunate persons who have not to consider the question of £ s. d., each print, measuring 8 by 8, costing 25 5s.

When I speak of a "partial enlargement," I mean one in which

certain parts of the picture are—during the enlarging process—covered with a “mask” and completely effaced. Take, for example, the photograph of a pretty girl in ordinary evening dress; the photographer decides to make a picturesque study, and wishes to introduce a soft-lace fichu and large plumed hat; also some indication of an artistic background. In this case a clear negative is made from the photograph, and from this a very carefully arranged enlargement, on rather smooth paper. An important point is that this enlargement should be of good size—in fact, the larger the better—because when the final negative is made the great reduction will give exquisitely fine effects.

To return to the enlargement; a long exposure is necessary with slow paper and a very small stop, and with a couple of pieces of paper, cut to required shape, the dress and part of the hair can be softly effaced. When the enlargement is finished and quite dry the fichu and large plumed hat can be carefully drawn in with a pencil or crayon, and also the slight background. The picture must be finished in every respect, and delicate pencil lines used to join sketch with photograph. Then a clear negative must be made, from which any number of prints can be taken.

#### FORTHCOMING EXHIBITIONS.

1907.

January 14 to 26: Royal Institute of Fine Arts. Entries close January 10.—Sec., J. Lizars, 101, Buchanan Street, Glasgow.

January 24 to 26: South Essex Camera Club. Entries close January 17.—Sec., T. Mitchell, 180, Browning Street, Manor Park, E.

January 31 to February 2: Nelson Photographic Society.—Sec., Henry H. Beetham, 98, Brunswick Street, Nelson.

February 6 to 7: Cowes Camera Club. Entries close January 23.—E. E. Vincent, 4, High Street, Cowes, I.W.

February 11 to 14: Cripplegate Photographic Society.—Sec., J. B. Iarnham, “Chafford,” Old Church Road, Chingford.

February 12 to 23: Sheffield Photographic Society.—Sec., J. W. Wright, 62, Vale Road, Sheffield.

February 13 to 15: Northern Tasmanian Camera Club.—Last day for entries, December 31, 1906. Secretary, F. Styant-Browne, 112, Brisbane Street, Launceston, Tasmania.

February 20 and 21: Royal Albert Institute, Windsor.—Hon. Sec., Mr. J. W. Gooch, 9, High Street, Windsor.

February 22 to March 4: Norwich and District Photographic Society.—Sec., J. T. Tanner, The Lodge, Norwich.

February 23 to March 2: Birmingham Photographic Society.—Sec., Lewis Lloyd, Norwich Union Chambers, Birmingham.

February 25 to 28: Worthing Camera Club. Entries close February 16.—Sec., E. F. H. Crouch, 11, South Street, Worthing.

February 26: Norwich and District Pho. Soc. Entries close February 12.—Sec., J. T. Tanner, The Lodge, Bowthorpe Road, Norwich.

February 27 to March 2: Nottingham Camera Club. Entries close February 14.—G. R. Cranch, St. Jude's Avenue, Nottingham.

March 2 to 9: South London Photographic Society.—Sec., W. L. White, Bank House, Ladywell, London.

March 6 to 9: Wearside Camera Club. Entries close February 20.—Octavius C. Wilmot, 297, High Street, West, Sunderland.

March 14 to 23: Leicester Photographic Society.—Sec., W. Murray, 60, Melton Road, Leicester.

March 22 to April 13: Northern Photographic Exhibition.—Sec., C. F. Inston, 25, South John Street, Liverpool.

April 17 to 19: Belfast Y.M.C.A.—Sec., J. W. Bushey, Y.M.C.A. Camera Club, Belfast.

April 29 to May 14: Photographic Society of Ireland.—Sec., R. Benson, 35, Molesworth Street, Dublin.

February 23 to March 16.—Scottish Salon. Entries close January 31. Receiving day for pictures, February 11. Sec., R. Milne, “Linndale,” Potterhill, Paisley.

## Patent News.

*Process patents—applications and specifications—are treated in “Photo Mechanical Notes.”*

The following applications for patents were made between December 10 to 12:—

**SILVER PRINTS.**—No. 28,067. Improvements in printing and developing photographs on silver chloride papers. Edward John Browne, 37, Moorfields, Liverpool.

**SHUTTERS.**—No. 28,174. Improvements connected with photographic shutters. Walter Frederick Giles, c/o Mrs. Thorp Wilsom, Alton, Hants.

**DEVELOPING APPARATUS.**—No. 28,305. Improvements in magazine developing cameras. Louis Mandel, 100, Wellington Street, Glasgow.

**MOUNTING PHOTOGRAPHS.**—No. 28,312. Improvements connected with the mounting of photographs and mounts therefor. Alfred Odell, 55, Chancery Lane, London.

**HALATION.**—No. 28,376. Improved means for preventing halation in sensitised photographic plates. Johann Hartlett, 31, Bedford Street, Strand, London.

**LENS MEASUREMENT.**—No. 28,502. Improvements in lens-measuring instruments. H. H. Lake for Franklin Hardinge, U.S.A.

**FILM CHANGERS.**—No. 28,543. Improvements in the cases or packs of photographic films or plates, and in the method of loading and changing same. Fred Hilton and Arthur Brown, 5, Corporation Street, Birmingham.

**WASHING AND DRYING RACK.**—No. 28,667. Improved device for suspending photographic plates for the purpose of washing them. Frederick Harrison, 19, St. Dunstan's Hill, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**BROMIDE PRINTER.**—No. 13,798. The invention relates to an apparatus for printing photographs by means of artificial light. The printing frame is that which forms the object of the application for English Patent, No. 13,799, filed June 15, 1906.

After sensitive paper and negative have been placed in frame

13 and printing frame 13 has been pushed back under roller 15, the handle lever 9 of reflector 6 is turned from the inoperative position through 45 degrees, whereby the reflector is opened at the same angle, blade spring 8 being tensioned at the same time.

Reflector 6 is secured in this position by spring catch 25, which snaps into the opening of arm 10 of the reflector. To remove the copy from the cliché after it has been sufficiently exposed to the light rays, pusher 11 is pushed and arm 10 thereby released from spring catch 25 and the reflector 6 pressed into frame 24 by blade spring 8, thus closing the opening 20. Printing frame 13 can now be pulled out from under the pressing roller 15 and the photograph taken out of frame 13. Hermann Müller, 6, Landfriedstrasse, Heidelberg, Germany.

PRINTING FRAMES.—No. 13,799, 1906. The invention is for a frame into which the negative and the printing paper can be rapidly placed and removed. The main frame is made to slide under a

roller, and when moved in this way has the back *n* pressed down on the paper by the springs, *m*. On pulling out the frame, *g*, again, the back is automatically raised. Hermann Müller, 6, Landfriedstrasse, Heidelberg, Germany.

## New Books.

"The Wellcome Photographic Exposure Record and Diary." 1907. London: Burroughs, Wellcome, and Co. 1s.

We have in the past said innumerable good and true things of this annual exposure notebook, and therefore we have only to point out that the present issue shows no marked departure from recent ones in order to bestow high and well-deserved praise upon the 1907 volume. All of which the latest issue merits even more than its predecessors, since it embodies a few improvements and additions worthy of note, and enhancing the usefulness of the Diary. Messrs. Burroughs, Wellcome, it is evident, are at a loss to make much of a showing of these new features, because, in sober truth, they have done their work so thoroughly in past years that little remains which can be usefully added to a volume intended as a pocket companion of the photographer every day of the year. Their failure is merely an admission of their record of assiduity. Yet they have taken a step for which no doubt many users of the diary will thank them. They have added a table of development factors for use in the Watkins system. The table is separately printed on a card which may be hung in the dark room, to be at hand throughout the photographer's practical work. It gives the factors of ten "tabloid brand" developers, and is to be used in reference to the greatly amplified directions for time or factorial development which appear in the text of the diary.

The other improvements include new drawings of typical subjects as a guide to exposure, an increased space for exposure records of exposures, and a revision, very up-to-date, of the speeds of the commercial gelatine plates. Messrs. Wellcome's table of these latter is the most complete extant. We see that they also give a table of conversion of their speed numbers into Watkins and Wynne, which will be useful to those who think of plate speed in terms of one or other of these quantities. The relation of Watkins to Wynne is apparently based on the rule that the square root of the Watkins number multiplied by 6.4 is the Wynne number, although the table exercises excessive caution in some of its conversions.

We ought to add for the benefit of the minority who do not know

the Diary that the included exposure calculator is in a most simple solution of a beginner's difficulties, and short of an actinometer, as good an aid as a novice can have. We can imagine Messrs. Burroughs Wellcome saying "Better," but we will not argue the point with them.

"Deutscher Camera-Almanach." Edited by Fritz Loescher. Berlin: Gustav Schmidt. 3s. 6d.

This is the third annual appearance of this yearbook, which is specially intended for amateur photographers. It contains a series of articles by well-known writers, a very large number of half-tone illustrations, and a three-colour frontispiece. Many of the half-tones are from monochrome and coloured bi-gum prints, and the results are extremely heavy and unsatisfactory, leading one to think that they do not convey the slightest idea of the originals themselves. The articles, however, are for the most part well written notes on topics directly bearing on the photographer's practical work, and we would mention especially the one showing the latitude at the command of the worker who prints in bromide.

"FAULTS IN NEGATIVES."—An addition has been made by the Imperial Dry Plate Company, Ltd., to the technical literature which they issue to their patrons in a booklet bearing the title "Faults in Negatives," and describing the defects which mar the negatives of the inexperienced. The causes of spots and markings, of mottlings, stains and frilling, and of other ills which afflict negatives, are concisely set forth, accompanied by a few reproductions which should be particularly valuable in supplying a comparison for the uninformed person. We have no doubt that the Imperial Company will send a copy of the booklet to anyone who applies to them.

THE PHOTOGRAPHIC LENS.—A second edition of a German work which we should like to see in English—despite the many works already published—has been issued by the house of Herr Gustav Schmidt, Berlin. The volume is "Das Objectiv," by Dr. E. Holn, and its special feature is the numerous illustrations showing by actual photographs the effects and defects of photographic lenses. The labour expended on these photographs alone must represent a large expense. The firm of C. P. Goerz, Berlin, has prepared a large number of them. The price of "Das Objectiv" is 2s.

## New Materials.

Jewelling Powders. Made by Reinemann and Co., 7, New Zealand Avenue, Barbican, London, E.C.

The jewellery or tinselling of photographs, particularly of picture postcards, being now a regular branch of trade, it is not surprising that firms should specially lay themselves out to supply the photographer with the materials exactly suitable for his work. The trader, fortunately, is not harassed with artistic considerations, otherwise he would not be placing such facilities at photographers' doors. On the contrary, he recognises that commercial advantages of some importance are involved in the use of the jewellery process, and the photographer will realise them, too, when he appreciates the cheapness of the labour needed for the work, and the enhanced prices which a jewelled or tinselled card will fetch. Holders of stocks of picture-postcards, which for some reason have proved unsaleable, have employed the jewellery powders to embellish the cards, and have had the satisfaction of seeing them purchased by the kind British public. In other ways, too, the photographer can use the jewel colours, for example, for calendars, Christmas cards, advertisement circulars, in short, for any purpose or on any occasion when the rich embellishment of a photograph may render it more desirable in a customer's eyes. The 'tinselling process is very simple, as follows:—A fixative solution of the nature of fish-glue is daubed on to the prints with a glass pen, that is, with a glass tube drawn out to a fine point. The jewel powders are then dusted on, the surplus immediately swept off, and the cards set up

to dry. The only part of the process where any skill whatever is required is in the markings of the prints with the fixative, but even this procedure may be simplified and adapted to the most unskilled labour by the use of a jewelled card as copy, or by means of a stencil, through which the fixative is applied. The jewel powders submitted to us are of three kinds, designated by the marks 19/80, No. 15, and 31/7. The two former are of much greater brilliancy than the latter. No. 15, too, is much more highly coloured than the first named. No. 31/7, on the other hand, is a different powder, the peculiar florescent effect of which is only seen when the card is at a particular angle. The powders are supplied by weight in the separate colours, or a set of colours with other accessories may be obtained.

Messrs. Reinemann, we might mention, are manufacturers of a special adhesive window decoration, sold as the "Diaphan," and applied to any glass surface simply by moistening with water. The material is sold in the roll, and some of the specimens we have seen were such good imitations of ground glass that we immediately made a note of the material for the benefit of photographers requiring something of the kind for obscuring the glass in their studios or other parts of their establishments. Messrs. Reinemann do not supply the material retail but refer their customers to local decorators or oilmen.

### CATALOGUES AND TRADE NOTICES.

THE Service Photographic Company, 292 and 293, High Holborn, London, W.C., have now on sale a large selection of second-hand photographic apparatus, chiefly cameras and lenses, a list of which they send us, specifying the items more fully than is usually done in bargain catalogues.

MESSRS. R. AND J. BECK, of 68, Cornhill, London, E.C., have just issued a more than usually interesting list of the photographic goods manufactured by them. Lenses and cameras, in the manufacture of which Messrs. Beck have specialised, occupy the chief portion of the list, which runs in all to 216 pages. It contains particulars of Messrs. Beck's offer to test shutters of any make for speed.

THE Halifax Photographic Company, Halifax, have issued a "B" edition of the list of their manufactures under the title of "Art Photographic Encyclopædia." The chief specialty of the firm is, probably, gaslight and bromide papers and postcards, both of which, in addition to gelatine and collodion P.O.P., they place upon the market under the trade mark "Lillywhite." The "Encyclopædia" gives the full working directions for these materials, and is on that account alone a convenient reference volume. It also describes the trade work department of the firm, and mentions a "Nonfrill" compound for addition to hypo in order to produce a hardening and fixing bath. The list will be sent free to any of our readers who apply for it.

PHOTOGRAPHY by Electrical Connection.—In reference to our recent paragraph as to the word which may be used to describe the process invented by Professor Korn, a correspondent sends us "photography," and "photoelectricography," neither of which, we must confess, impress us as an improvement on the word coined by ourselves in the first instance, viz., "telectrophotography," which etymologically and euphonomously is preferable.

STAGE Photographs.—The "Daily Mirror," in a brief and breathless article, informs its readers that it is showing "something new and important in photography." The "something" is a series of photographs of a moving stage performer, said to have been taken with an ordinary hand-camera, an ordinary lens, and ordinary plates. The photographs are satisfactory as regards sharpness, but no better than the snap-shots of stage performers which appeared in our pages six months ago illustrating Mr. Arthur Payne's article on the subject. Similar photographs, of better quality, are reproduced in "Penrose's Annual" from negatives made by Mr. J. E. Gould. Apparently the new and important discovery of the "Mirror" is the use of a bathed plate.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

WARRINGTON PHOTOGRAPHIC SOCIETY.—Lecturing for Messrs. Wellington and Ward, Mr. Harry Wade referred to the new self-developing plates of the Elstree firm to be placed on the market in the New Year. The grades would be exactly the same as at present—"Speedy," "Iso-speedy," and "Landscape," with the developer in the form of a soluble backing, requiring the use of water only for development, the developer backing would be practically non-halative. Mr. Wade then proceeded to develop a half-plate which had been exposed in an ordinary room. Using 2 oz. of cold water, the image appeared in a little over a minute, and full development was complete in five minutes. It was explained that the temperature of the water should be not less than 62 deg. Fahr, as, using a lower temperature, a plate which had received correct exposure would on development have the appearance of under-exposure. The easy method of development, and the clean, sparkling results of Mr. Wade's efforts strongly appealed to those present.

A series of slides made on the new S.C.P. plates made from self-developing negatives were then shown on the screen, the demonstrator afterwards showing his method of obtaining a range of tones on these plates from black to sepia with a simple hydroquinone developer made up as follows:—

Water .....	20 oz.	Dissolve in order given.
Sodium sulphite .....	500 grains	
Hydroquinone .....	80 grains	
Sodium carbonate .....	500 grains	

#### B.

Potassium bromide .....	10 per cent. solution.
-------------------------	------------------------

Tone Required.	Exposure.	Developer.
Black	15 seconds	2 ozs. A.
Warm Black	30 seconds	2 ozs. A, 3 drops B.
Brown	60 seconds	2 ozs. A, 6 drops B.
Warm Brown	2 minutes	2 ozs. A, 12 drops B.
Red Brown	4 minutes	2 ozs. A, 24 drops B.
Red	8 minutes	2 ozs. A, 48 drops B.

LIGHT.—Incandescent gas at 12 in.

The demonstration was in every way successful, Mr. Wade being heartily applauded at the close.

**SHANGHAI Amateur Photographic Society.**—On November 8, Mr. J. Mencarini delivered a lecture on the marriage of H.M. the King of Spain, at which function Mr. Mencarini attended in the capacity of Second Secretary to the Special Embassy despatched by H.I.M. the Emperor of China as his representative. The numerous pictures thrown on the screen included a couple showing the havoc wrought by the throwing of the bomb. At the close of Mr. Mencarini's exhibition a number of Chinese and Burmese pictures, taken by Messrs. Carter and Bevan, and others members, were thrown upon the screen.

Council): I understand Bridlington makes the same charges without any Act of Parliament. We rely upon our lease with the Lord of the Manor. The Town Clerk of Scarborough (Mr. D. A. Nicholl), in reply to his Honour, said although the Scarborough Corporation had an Act they did not rely upon it to make charges, but upon their powers as Lords of the Manor and the rights of freeholders under the common law. His Honour reserved judgment until the next Court, and by consent agreed to amend the claim, so that it might include a question as to trespass, on the understanding that the District Council paid Mr. Doran's reasonable expenses for the day.

#### NEW COMPANIES.

**DENTON AND Co., LTD.**—Capital £500, in £1 shares. Objects: To carry on the business of photographers, photographic and general printers, photo-lithographers, manufacturers of and dealers in photographic apparatus, chemicals, and accessories, postcard publishers, etc. No initial public issue. Registered without articles of association.

## Commercial & Legal Intelligence.

**A BRISTOL Bankruptcy.**—Harold Edward Brightman, Colston Street, Bristol, photographer, made an application for his discharge at the Bankruptcy Court, last week, before the Registrar. Mr. Frank Richardson appeared for the debtor, who attributed his failure to bad trade. The Official Receiver, in reply to the Judge, said there was no peculiar feature in the case. The order was granted subject to two years' suspension.

**FRANCIS EDWIN ELLIS**, of Ivycroft, Stockdale Road, Streatham, a photographic artist, applied for his discharge from bankruptcy at the last sitting of the Wandsworth County Court. His case has been already reported on page 218. A solicitor who appeared for debtor asked his Honour to grant Mr. Ellis his immediate discharge. He pointed out that debtor's failure was due to the action of Mr. Hayward, his late partner in business. In consequence of this, followed by Chancery proceedings, Mr. Hayward left the business, and was ordered by the High Court to pay Mr. Ellis £1,218. He was extremely annoyed at this result of the legal proceedings, and filed his petition. His action forced Mr. Ellis into bankruptcy also, but Mr. Ellis' failure was due to circumstances over which he had no control. The Judge granted him his immediate discharge.

**A KNOWLEDGE of Photography for £2.**—At the Halifax Borough Court, last week, a man, aged about forty, giving the name of William Williams, and describing himself as a photographer, of no fixed abode, was charged on remand with obtaining £2 by false pretences from Ernest William Nelson, of Holborn Street, Leeds, in April last. The accused was not traced until the 14th inst., when he was apprehended at Lancaster. Prisoner offered to teach the prosecutor the business of a photographer for £2, representing himself as the proprietor of several photographic businesses. He afterwards absconded. Inspector Bradley deposed to tracing the prisoner to Lancaster, where he apprehended him on the 14th inst. The accused, who reserved his defence, was committed to the quarter sessions for trial.

**RAPID Photo Printing Company, Ltd. (London).**—Issue on December 5 of £300 six per cent. debentures, part of series created July 2, 1906, to secure £10,000, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. Total amount previously issued of same series, £6,600.

**SEASHORE Photographers.**—A case of special interest to seaside resorts came before His Honour Judge Dodd at the Scarborough County Court on December 18, on a claim by the Sherburn Rural District Council for 30s. from Geo. H. Doran, photographer, Filey, balance of the amount agreed to be paid for a photographic stand on Muston Sands. The Council also asked for an injunction to restrain defendant from using the sands as a photographer. The defence set up the contention (1) that plaintiffs had no authority to enter into the lease under which they got their powers, and (2) if they got their powers in a proper or statutory way they could not make any charge. Filey and Scarborough, said Mr. Wray, who appeared for Doran, got their power to make charges on the sands by Act of Parliament. Mr. Perks (for the Rural

## News and Notes.

THE death took place at Godalming last week of Mr. George West, who for many years had carried on the business of a photographer in the High Street.

**A STUDIO for the Blenheim Club.**—A circular from the Blenheim Club (with which the old Camera Club is now amalgamated), announces that a site for a studio has been obtained in Jernyn Street, and that steps are now being taken to fit it out for the requirements of the members of the Club; every effort will be made to have it ready for use early in 1907. This convenience will no doubt be appreciated by photographic members of the Blenheim, who now have at their disposal all the facilities which a photographer can desire, short of an establishment of his own, in addition to the comforts of a club in the heart of the West End.

**PLANE Development.**—Dr. E. W. Buchner, of Darmstadt, states in the "Photographische Rundschau" that fourteen years ago, when he was a beginner in photography, he busied himself with the question as to whether the upright position of the plates, as is usual in stand development, was a necessary condition, and whether the horizontal position was not equally as satisfactory. His experiments led him to believe that the horizontal position was applicable, but, as he obtained several inexplicable markings, the method was abandoned.

At a meeting of one of the Frankfort photographic societies at that time, he asked whether it was absolutely essential to place the plates in a vertical position for stand development, and pointed out that the process should be equally effective if the plates were horizontal. Details of his experiments and results were shown. The answer, accompanied by some laughter, was, Obviously this method of development could only be effected with the plates in a vertical position, or otherwise why should it be called "stand development"? Thus the whole matter was settled so far as the author was concerned. Dr. Walter's article was therefore of special interest to the author, and explained his failures, which were obviously caused by taking the plates out too frequently for examination. As, however, the essential requirement for plane development is that the dish shall be perfectly level, most dark-room benches would be, as a rule, unsuitable.

Further experiments have now been made by the author, and perfect negatives obtained. In comparative tests with "stand" and "plane" development, with equal duration of exposure and development, somewhat less dense negatives were obtained with the latter, the result of the more intense action of the bromide. With plates exposed for 1.40th of a second the duration of development was from twenty to thirty minutes. Care should be taken in plane development that when the developer is repeatedly used it should be well stirred up each time before a fresh plate is immersed, and the fresh plate should be gone over with a soft brush.

When a series of unknown exposures have to be dealt with, a separate dish must be used for each plate, and it would be as well if manufacturers would make shallow dishes for this purpose.

Where there is room enough a series of such dishes can be placed on a flat table and covered with a close-fitting cover.

Examination of the progress of development can then obviously be seen with a movable incandescent electric light or oil lantern. When one is cramped for room the author suggests a wood or iron stand with shelves one over the other. In both cases the use of clear glass dishes with an electric light underneath would be very advantageous to see the progress of development.

In all cases in which the time of exposure is known, and therefore the approximate duration of development with a very dilute developer is known from a preliminary experiment, the author prefers the upright developing tanks and to use the grooved rack, after removal of the handle, turned on its side.

If a preliminary trial has been made it is not necessary to lift the plates out for examination, as a too-prolonged development will not hurt, and plates developed too long or not enough can be easily corrected by intensification and reduction. The author considers that for this method of development it is absolutely necessary for the plates to be left perfectly quiescent till development is finished, and he has obtained excellent results with glycin as well as with pyrocatechin without sulphite, and warmly recommends the process.

**WRINKLES.**—In the current issue of "Camera Craft," Mr. W. G. Emery brings together some notes on dark-room matters, from which we may cull one or two extracts:—

"Washing Trays. I have been a photographer for a good many years, but I did not know how to make a durable oilcloth washing tray until I learned how at the Salem Convention three years ago. I made a set on my return home, and I have been using them continuously ever since. This little model I have will show you how simple is the process of making them. Cut the material for the tray to be when finished about 24 by 30, and 4 in. in depth. Nail the bottom boards on the sides, leaving the ends to be fastened on after the oilcloth is properly fitted. Next turn up the edges of the cloth so that it fits snugly against the sides and bottom of the tray; then, turning up the cloth at the ends, draw the corner laps or ears out past and around the ends of the side pieces. Nail on the end pieces with these corner ears still on the outside. The usual way is to fold these laps inside the tray. By this better method there are no projecting corners left inside the tray to be shortly worn through.

"Spotting Prints.—We all know what a tedious job is the spotting of photographs for delivery, and how difficult it is to put on just enough colour to cover up the defects. Most photographers use india ink and watercolours, put on with a spotting brush. I have all these things at home, but seldom use them, as I find that the quickest, simplest method is to use a carbon pencil, a Conté, similar to this one I am showing you. These pencils can be secured from any art store in varying degrees of hardness. I get the most satisfactory results from a No. 2. Try one, and you will seldom pick up a spotting brush in the future.

"Fixing Bath.—I used to be bothered a good deal keeping my fixing bath clear and in good working order. Some photographers make up a fresh bath every day, but some of us are in the habit of using the same bath as long as it will not float the negative. I now make up my bath as follows:—

Hypo dissolved in two quarts of water .....	1 lb.
Sulphite of soda .....	$\frac{1}{2}$ oz.
Acetic acid, No. 8 .....	3 oz.
Alum, pulverised .....	$\frac{1}{2}$ oz.

This remains clear for a month or more, and will harden the film sufficiently to prevent frilling or blistering in the warmest of weather."

"Home-made Mounts.—In the city where the photographer has only to go a few blocks to reach a stock-house, there is little, if any, bother about procuring any style of mount suitable to fill almost any kind of a special order. From my own experience I know that the country photographer is often up against a hard proposition when he has an order from an exacting customer, especially as to mounts. I have often booked an order that I would have otherwise lost by showing a simple home-made mount with deckle-edge insert; besides getting a little advance over prices previously quoted. These mounts are especially adapted for platinum or other non-curling papers. Five and eight ply cardboard in a variety of tints, as well as variously

tinted cover paper, can be procured at any of the stock-houses. In making the mount, select a tint of card and insert that which will harmonise with the print to be mounted. Cut the card panel-shaped, about 7 by 11 for cabinet prints, and cut out a cardboard form or die,  $\frac{1}{4}$  in. or  $\frac{3}{8}$  in. larger each way than the print. Emboss the mount by placing the die and the mount together face downward on a smooth table or pane of glass, and with an embosser follow around on the back of the mount, the edge of the form underneath. A knife handle, tooth-brush handle, or any similar article will do for an embosser. Cut the insert a little larger than the print and deckle the edges by bending them, in turn, over the edge of a board and simply cutting through the paper with a wood rasp. Brush a little glue around the edge of the insert and attach to the mount, and it will be ready for the print. Place the finished picture under pressure for a short time, and it will be ready for delivery."

## Correspondence.

- \* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### BRITISHERS—WAKE UP!

To the Editors.

Gentlemen,—I have just returned from a five years' stay in the East and during that time have had to professionally visit the chief trading ports of India and the Straits Settlements, etc. It is probably a well-known fact that we sailors, after the somewhat close confinement aboard, are in the habit, when off duty, of getting ashore to obtain a little amusement and recreation. One of the chief and harmless amusements out there is the cinematograph shows, and I should like to call the attention of those at home interested in such things to the existing state of affairs.

One frequently finds a rough shanty, or even a canvas tent, rigged up for these shows, and as sure as one sees that it is run by an Englishman we know it is not worth going to see. On the other hand, should the boss be a John Chinaman, or a Japanese, the show is excellent. The English exhibit is, as a rule, distinguished by unsteadiness, and an irritating shimmer (? flicker.—Eds. "B.J.P."), and dirty old films, with constant flashes of white lightning running through the pictures. If you go into an English show you are cramped for room, and the pictures are shown in silence.

Not so with a Jap or Chin show. Here you have plenty of room, are provided with a fan—quite a minor affair, but when the temperature in the shade runs up to 120 deg. Fahr., even a paper fan is acceptable. One has music—true, it is native, with more tom-tom and weird discords than harmony—still it is music. Then the pictures are absolutely steady, there is no shimmer, and no lightning, and each one is accompanied by appropriate noise. What I mean by this is best illustrated by taking one instance, where a duel is fought with pistols; at the exact moment one hears the crack of the pistols and sees one of the combatants fall. When shown by the English house there is none of this slow music and wailing of the fiddle, etc.

Surely, if such good shows can be given by the Japs and others, Englishmen could do it. It is not a question of price, because, in many cases, they are the same, or the native shows are cheaper, the prices varying from two dollars to four rupees, that is about five shillings in English, whilst the native shows may be about three shillings in some cases.

The business done by these shows is good. In one case I know it ran into over £70 a week. One never finds a good show with an empty or half-filled house.

Since I have been home I have seen two or three shows at your chief London halls, and they are no better, and in some cases worse, than the Jap shows out in the East.

Why cannot the English give us the best that can be got?—I enclose my card and remain, yours faithfully,

CHIEF ENGINEER.

## Answers to Correspondents.

*All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

*Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.*

*For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPH REGISTERED:—

G. Muse, "Walmerbank," Ladbroke. Photograph of Mr. and Mrs. Tom Kennedy.

**TUDIO QUERY.**—1. If a studio is built in garden, with an east light, will there be a good light; or will the shadow from the houses spoil the light? Could the sitter be placed at the north end of studio as in sketch? 2. What length of glass, how low down at side, and what width of glass in roof should there be? 3. Most suitable colour for painting inside, and colour and material for blinds? Could the following shape be about right?—C. H. OXBURY.

1. There will be a suitable light if the studio is erected as shown in the sketches. The sitter may be placed at either end, but perhaps the south end will be found the more generally useful. 2. Better have 5 ft. or 5 ft. 6 in. at either end, side, and roof opaque, and the rest glass, commencing about 3 ft. from the floor, and carried up to about 2 ft. from the ridge, as shown in sketch. 3. Any light, quiet colour, such as French grey. Dark blue or medium green for the blinds, serge curtains for the side, and window holland for the roof blinds. 4. Yes, quite right.

**USE OF NEGATIVE LENS.**—Will you inform me how to measure the focus of a negative lens?—W. SYKES.

One method is to neutralise the negative lens by a convex fill it acts like a plain glass. As this necessitates the trial of a large number of convex lenses, the following plan is better:—In an opaque card punch two small holes at about three-quarters of the diameter of the lens apart. Place in contact with the lens, and move the lens and card away from a sheet of white paper till the images of the holes are the same distance apart as in the card. It is also possible to place the negative lens in front of or in between the combinations of any ordinary lens and measure the resulting focus, and then calculate by the usual formula or the size of a known subject, such as a foot-rule, the focus of the negative lens.

**AMEL ON COPPER.**—I am asked to reproduce some designs on copper plaques, the image to be capable of standing a slight etch. Presumably I could use a formula such as is used for photo-engraving, and should be obliged if you can tell me the most suitable.—P. HOLR.

Innumerable formulae for such things exist, but the following can be relied on:—

Le Page's liquid glue.....	4 oz.
Egg albumen .....	1 oz.

Mix thoroughly, and then add the sensitiser, which is a 1 in 16 solution of ammonium bichromate. The necessary quantity for the above quantity of albumen and glue is:—

Bichromate solution .....	2½ oz.
Water .....	8 oz.
Ammonium citrate .....	25 gr.

Filter through flannel or linen and flow thinly over the copper. Development is effected with hot water.

**F. T.**—The life of all patents is fourteen years, and therefore the one in question is obviously void. With regard to the more recent ones, you can see whether the fees have been paid after

the fourth year, by referring to the fee registers at the Patent Office Library.

**S. L. M.**—The article appeared on p. 848 of our issue for October 27, 1905.

**A. B.**—Mawson and Swan, Penrose and Co., and Fuerst, make a specialty of the dyes.

**H. M. OSBORNE.**—The work has long been out of print. Your only plan would be to advertise for it.

**RUBBER SOLUTION.**—I have been trying to make a rubber solution of rubber in benzole, but find it merely swells up and will not dissolve. What is the reason?—CARBON.

The most probable reason is that vulcanised rubber has been used, whilst what is required is that known as masticated pure rubber. By far the simplest plan is to purchase a tube of cycle tyre cement or a tin of rubber solution at a rubber store and thin it down to the consistence of treacle with benzole, not benzoline.

**THREE-COLOUR CARBON PRINTS.**—Although carefully following the maker's directions, I find that my three-colour carbon prints in a short time frill up and part company. What is the cause, and remedy?—TRICHROME.

Our correspondent does not state whose tissue he is using, but this defect is frequently caused by using chrome alum in the gelatine cementing solution. This in time appears to tan the gelatine so as to cause the films to part company. Another cause of the trouble is using the gelatine solution too cold. If this is used fairly warm and the constituent prints are taken from water at about 80 degrees Fahr., there will be no difficulty. Another cause may be that the rubber is not all removed from the face of the prints.

**COPYRIGHT.**—Is it possible to mount several prints on one card and then copyright them as a whole, or must each be copyrighted?—C. A. WALKER.

If the idea is to make the individual prints merely parts of the whole, which is the picture, then it can be done. If, on the other hand, the idea is economy and the saving of the fees, then it is not permissible, but each picture must be separately protected.

**P. H. ALMER.**—Your only plan is to at once place the matter in the hands of a solicitor, and let him deal with the firm. We would only suggest that you must be quite sure of your facts, and take into consideration that you are not the first who has done this, and, therefore, your ideas may not have been infringed in any way.

**S. E.**—See the ALMANAC, p. 979, 1906.

**J. MARSHALL.**—The reference appeared under "Photo-Mechanical Notes," p. 1034, of December 29, 1905, and is indexed under "Collodion emulsion orthochromatic." It is obvious that you have overlooked it.

**MATT CARBON PRINTS.**—Is it possible to coat carbon prints with a matt celluloid varnish? If so, can you give a formula?—CARBON PRINTER.

There is no reason why the prints should not be coated with such a varnish, nor any reason why a sheet of ground glass should not be coated with ordinary celluloid varnish, and this used as a temporary support, when the outer surface of the celluloid would be matted. A matt celluloid varnish is a little difficult to make so that it will dry clear, but possibly the following applied thinly would answer:—

Celluloid .....	96 grains.
Acetic ether .....	1 oz.
Methyl alcohol .....	2½ oz.

Dissolve in the above order.

**THREE-COLOUR NEGATIVES.**—I am just starting three-colour work, and although I adhere strictly to the ratio of exposures given by the makers of filters and plates that I use, I find that at times either the red or green screen negatives are incorrectly exposed. This is judged by the results obtainable by carbon printing; and, further, when I have altered the ratios, I get better results. What is the reason of this, and is the ratio altered by the colour of the subject?—W. A. T.

No doubt the makers' ratios are correct, but these are given for daylight of normal spectrum composition, and the ratios

will not be altered by the colour of the subject; but should the daylight vary in character, the ratios would be at once upset. This was very clearly shown by Drs. Precht and Stenger in a paper which appeared in the "B.J." for March 24, 1905, p. 226, to which reference should be made.

**AMIDOL DEVELOPER.**—I am told by a local professional that he always uses alkaline amidol developer for his negatives, and he says that he can get more out of his plates with this than by any other method. He refuses, in a dog-in-the-manger fashion, to give me the formula, but offers to make the developer up for me, but at a rather high price. Can you give me a suitable formula, or should I buy it?—**AMATEUR.**

Everyone is at liberty to withhold any information that he may possess if he thinks fit, nor can anyone be blamed for trying to make a little money. Possibly, however, the following formula, which works well, will answer all requirements:—

Distilled water .....	20 ozs.
Sodium sulphite .....	100 grains.
Amidol .....	50 grains.
Caustic soda .....	10 grains.

Dissolve in the above order.

**RED TONES ON CC. PAPER.** Can you tell me how to obtain red tones on matt. cc. paper? I have tried several baths but have failed.—**TRADE PRINTER.**

Almost any bath can be used provided that it is diluted with an equal quantity of water so as to restrain its action and the duration of toning is cut down. The following has, however, been specially recommended:—

Prepared chalk .....	$\frac{1}{2}$ oz.
Chloride of gold .....	1 grain.
Water .....	20 ozs.

Shake well and allow to settle and use the clear portion only. The tones given by this are reddish brown, but real red tones are obtainable with,

Uranium nitrate .....	20 grains.
Thiosinamine .....	100 grains.
Distilled water .....	20 ozs.

The prints must be thoroughly washed both before and after toning.

**RUSTY BURNISHER.**—My roller burnisher has got rather scratched and rusty. Is there any simple way of cleaning the same?—**S. WALES.**

The only thing to do is to use a fine-grade emery cloth with longitudinal strokes till the scratches and rust are removed. Then with the finest emery flour and oil go over the whole again till it is bright. This is a somewhat long and tedious job without a lathe, and it would be better to send it to an engineer, who would soon be able to clean and polish it for you and at no heavy cost.

**J. O. B.**—We cannot undertake to do what you ask. Your best plan will be to consult the small advertisements or insert one yourself.

**LENS STAINS.**—I have just bought an old portrait lens very cheap, and the front combination shows some small trees and curious coloured stains, which apparently are in the glass itself. Can I remove them, and how?—**PORTRAIT LENS.**

No doubt these are due to the Canada balsam between the two glasses of the front lens, and are frequently seen in old lenses. It is quite possible to do it oneself, but, as a rule, it will be done better by a lens-maker. The lens must be removed from its cell and placed in luke-warm water and left for about five minutes, and then more hot water added very gradually, giving the glass time to warm up, or else it will crack. After some time it will be found that the glasses can be slid apart, and they can then be thoroughly cleaned with methylated spirit or ether and polished and recemented together by placing some Canada balsam in the concave lens and pressing the convex down on to it, using heat, if necessary, to obtain close contact, and then cleaning off excess and putting into the cell.

**ENLARGING LENS.**—In using the lens from an optical lantern for enlarging I find that I cannot get the edges of the enlargement sharp at the same time as the centre. Can anything be done, or would an anastigmat give me better results?—**AMATEUR.**

The lenses generally used for optical lanterns are of the Petzval portrait type, and will not give both centre and edges sharp. The results can be frequently improved by separating the back lenses a little more, which can be easily done with strips of cardboard placed between them. An anastigmat would certainly have a flatter field, and in all probability would cover sharply at full aperture. In taking the portrait lens to pieces care should be taken that the back lenses are put together again in their correct positions—that is, with the convex lens outside and the flatter side of this, too, away from the concave.

**YELLOW BROMIDE PRINTS.**—Will you be good enough to tell me if you can suggest a method of toning a bromide print to a chromatic yellow colour, similar to the yellow carbon tissues used in the three-colour work?—**C. H. MADDEN.**

Bleach the print in the lead ferricyanide solution used for negative intensification as per p. 968 of the "Almanac," and after the usual washing in water, acidified with nitric acid, immerse in solution of potassium chromate.

**ELECTRIC LIGHT.**—Can good work be done by electric light in a room 27 ft. by 12 ft. in height? Would one or two lamps be required of 12 amperes to light a group of a dozen or more persons, or perhaps you can suggest some better light?—**E.L.**

The room is a most convenient size as to length and width, but it will be difficult to get an arc lamp high enough to give really good illumination over a group of a dozen people. Ty lamps might be employed, working in series, and the consumption of electric energy should then be only a little more than with one lamp of rather larger size, as less energy would be absorbed by the resistance. We print this week a leading article on this question to which we may refer our correspondent.

**CITRATE RESTRAINER.**—Will you please give the formula for the citrate method, mentioned in your issue of December 21, page 1,001, restraint for an over-exposed negative; developer, pyro soda.—**H.C.H.**

The usual method is to add some citrate of the alkali used in the developer; in the case in point this would be the citrate of soda, which may be obtained in the dry form, but as it is extremely deliquescent it is preferable to make it by neutralising carbonate of soda with citric acid, according to the following formula:—

Citric acid .....	280 grains.
Bicarbonate of soda .....	345 grains.
Or Carbonate of soda (crystal) .....	580 grains.
Distilled water to make .....	4 ozs.

The above are the approximate quantities of the sodas required, but the solution should be neutral to litmus after being A fairly large measure should be used for this as the solution is considerable effervescence. The result will be a 1 in 10 solution of sodium citrate. It is not advisable to make weaker as it has a tendency to grow mouldy. About 30 to 60 minims should be used for every ounce of developer.

**SAXON.**—The rule you give only applies to very thin lenses. With the deep-curved lenses used in the modern anastigmats it does not apply in many cases.

**\* \* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## British Journal of Photography.

Charge for PREPAID ADVERTISEMENTS of Four Lines (each Line containing about Seven Words) of the following Classes ONLY:

Photographers Requiring Assistants.  
Operators, &c., Wanting Situations.  
Photographic Premises to be Let or Sold.  
Second-hand Photo. Apparatus for Sale.  
Miscellaneous Trade Announcements.

1/- Each  
Insertion  
Net  
Prepaid.

Each Additional Line, Sixpence.

Those wishing to have their Advertisements addressed to initial letters, c/o BRITISH JOURNAL OFFICE, may do so by remitting 6d. extra per insertion, each advertisement, for receiving and forwarding replies; but no charge is made if letters are called for.

DEPOSIT.—When dealing with strangers our Deposit System renders the transaction safe, and the commission is trifling compared with the protection thus afforded. The purchase-money must be deposited with the publishers, HENRY GREENWOOD & CO., 24, Wellington Street, Strand, W.C., and all Cheques, Money Orders, &c., made payable to them. Acknowledgment is sent to both parties, and deposit is held until receipt of advice that goods have been received and found satisfactory, in which case the amount deposited is forwarded to the seller, less a commission of 2½ per cent. (minimum, one shilling). If goods are not approved the publishers wait original owner's acknowledgement of their safe return before refunding the deposit, the usual commission being deducted. All disputes or questions arising must be settled between the contracting parties.

**SPECIAL NOTICE.** THE LATEST TIME FOR RECEIVING SMALL ADVERTISEMENTS IS 2 O'CLOCK P.M. ON WEDNESDAYS for insertion in the current week's issue.

LARGE ADVERTISEMENTS should reach the Publishing Office not later than Tuesday.

\* \* Communications relating to Advertisements and general business affairs must be addressed to

**HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.**

## Situations Wanted.

**A GENTLEMAN**, just returned from abroad, desires position as Operator or Manager in England; 10 years' practical experience.—"R. E.," 31, Bartram Road, Crofton Park, London, S.E.

**A YOUNG MAN** (21) wishes to assist in studio in his spare time; moderate remuneration; Kensington district preferred.—Address "O. F.," 53, Abingdon Road, Kensington, W.

**ADVERTISER** (28), smart, desires Berth as Operator-Retoucher, &c.; could manage; thoroughly understands business throughout; South preferred; highest refs.; sal. mod.; disengaged Jan. 1.—"C.," 113, Wanstead Park Road, Ilford, Essex.

**ARTIST**, B. W. Oils, Crayons, large or small work, wants Engagement; quick worker.—"Artist," care of Chas. Lucas, 121, Haydon's Park Road, Wimbledon, Surrey.

**AS Operator and Manager**; artistic; quick and businesslike; well up in all branches; not afraid of work. Parkes, Kate Villa, Bognor.

**AS Operator-Retoucher** or Manager; disengaged; London preference; good references; good class.—A. Howell, 100, Chamberlayne Wood Road, Willesden, N.W.

**ASSISTANT**, of good experience, desires Engagement; excellent references; moderate salary.—Address "A. C.," 145, Lewisham Road, Lewisham, S.E.

**EXPERT Operator-Retoucher**, Regent Street firm, seeks most as Manager or otherwise; thoroughly competent in all branches; refs.—Address "V.," 101, Bovill Road, Forest Hill, S.E.

**IMPROVER**—Young man seeks Situation in good studio, with outdoor trade preferred; has whole and half-plate outfit; wages moderate.—Parken, Lapthorne, Modbury, South Devon.

**MIDGETS**—First class man now at liberty; take entire charge of studio; finish work throughout; 12 years' exp.; highest references; will serve a good employer well.—"C. F.," 1, Stamford Street, Leeds.

**OPERATOR and Retoucher** disengaged; many years' first-class West-End experience; excellent references, &c.—Address "H.," 80, Goldhawk Road, Shepherd's Bush, W.

**PRINTER**, expert in Sepia and Black, Plat., C.C., used Cosway borders; 11 years' experience.—P. Ward, "Firs," Caversham Heights, Oxon.

**RECEPTIONIST-CORRESPONDENT** requires Re-appointment in high-class studio; retouching, finishing, small and large work, tinting; spec. and testis. "Receptionist," 352, Clapham Rd, London, S.W.

**SMART General Assistant** or Bromide Printer requires Situation about middle of January; good all-round hand (except retouching).—Victor Buckipitt, Escoback, Wells Road, Bath.

**STUDIO and Dark-Room Assistant** desires Remuneration with a first-class house only; age 21; good developer.—"E. W. C.," 33, Cotlands Road, Bournemouth.

**YOUNG MAN** (18) wishing to improve in Operating, Retouching, and B. and W., desires Engagement in good house, London.—X. 9, 24, Wellington Street, Strand.

## Situations Vacant.

**ARTIST** wanted, thoroughly experienced in finishing 20 x 16 Bromide enlargements in B. and W. and A. and A. applications; must also be competent and experienced in training and teaching beginners to supervise the work of other artists, and to generally manage the finishing department. Only those need apply who, by references or testimonials, can prove their ability and experience.—Send full particulars, with specimens of work, to The Great Britain Art Co., Grosvenor Street, Manchester.

**ARTISTS** wanted, experienced in finishing 20 x 16 Bromide enlargements in B. and W.; must be used to quantities and have their own A. and A. Positions vacant in Manchester, Wolverhampton, Leeds, Liverpool, Hull, Newcastle, Sunderland, Middlesbrough, York, &c., &c.—Send full particulars and sample to The Great Britain Art Co., Grosvenor Street, Manchester.

**CONTACT Bromide Printer** required; must be thoroughly experienced in handling large batches of good work.—Full particulars to 96, North End, Croydon.

**GOOD Operator-Retoucher** required for branch studio; quick trade; open Sundays; no stamps; perm. to a suitable man; wage, 30s. and com. Photo. of self and full particulars.—X. 7, 24, Wellington St., Strand.

**LESSONS** in Negative Retouching, B. and W., Colour Work, Miniature Painting, Tinting. Highest class tuition. *Slow retouchers, &c., quickened and improved.* Lessons by day, night, or by post. B. and W. and colour; pupils also taught the new, quick method of Stippling working (regd.), and retouching pupils the use of *Negafake* pencils (regd.). A pupil taught by T. S. Bruce writes: "You will be pleased to hear I am at Messrs. W. & D. Downey's the Court Photographers of Ebury Street, S.W. I am exceedingly obliged for your skill and attention in teaching me so effectually as to secure such a place." Original letter can be seen if desired. The Editor *British Journal of Photography* stated in that paper "another pupil's work." We congratulate both tutor and pupil.—Address T. S. Bruce, Artist (Est. 1885), 4, Villars-on-Heath, Vale, Hampstead, London. (See pp. 27 to 30 B.J.J. Almanac.)

**MATALL AND CO.**, 126, Piccadilly, have a vacancy for pupil; must be well educated, with artistic ability.

**MIDGET Stamp Trade**.—Man or man and wife for branch; give particulars of previous engagement.—Farr, 168, Hockley Hill, Birmingham.

**MIDGETS**.—Wanted, reliable man for branch; must be used to stamp trade. State experience and wages required.—X. 8, 24, Wellington Street, Strand.

# Toned Royal Pictures

Other Brands  
Kodak  
Bromide Papers:  
PERMANENT  
LATINO-MATTE  
KODAK  
VELVET

equal the best carbon prints and are constantly securing the highest honours at photographic exhibitions, where they figure in ever-increasing numbers. . . . You can always pick out a "Toned Royal." . . . Exhibitor, judge and visitor are impressed at once by the rich effect, the beautiful surface, the colour and the transparent shadows of these prints. . . . Apart from this, Royal Bromide is easier to manipulate than carbon: it answers equally well for contact prints or enlargements, and the latter can be made direct from small originals without the intervention of enlarged negatives.

## KODAK SEPIA TONER

# What You Want!

Thoroughly reliable well-tested plates, with a wide latitude for under and over exposure. Makes good negatives. When only a minimum exposure can be given . . . .

## BARNET RED SEAL

is just the very thing. Although a very rapid plate (350 H. & D.), yet it allows such a latitude in exposing that under or over exposure is practically never known. The very plate for uncertain weather and dull days in the studio.

## BARNET EXTRA RAPID.

Another equally reliable, all-round plate, when very quick exposure is not necessary. Speed 200 H. & D. Makes soft, rich negatives. . . .

ELLIOTT & SONS, LTD.,

BARNET, HERTS.

## PROGRESS!

is the watchword of every up-to-date Professional. He is always  
alert to grasp the opportunity that assists in the furtherance of  
his business, or helps in any measure to make it a lucrative  
success.

THE  
THORNTON-PICKARD  
STUDIO SHUTTER.

PRICE from 20/6

is indispensable to every well-equipped  
Studio, and only by a practical test can  
its superior features be appreciated. It is

PRACTICALLY NOISELESS IN WORK.  
ABSOLUTELY WITHOUT VIBRATION.  
ENTIRELY UNDER OPERATOR'S CONTROL.  
MADE ON THE ROLLER-BLIND  
PRINCIPLE.

It gives exposures of 1/2 sec. and longer  
duration, and is fitted with a Special  
Locking Tap to keep Shutter open for  
lengthy exposures.

MANY PROFESSIONALS who for a long  
time were content with inferior and  
second-rate arrangements have been  
more than surprised at the results ob-  
tained with the Studio Shutter.

## ONE PROFESSIONAL SAYS:

"Your Studio Shutter gives me the greatest satisfaction.  
It is an immense boon in every way, allowing one to get  
pictures which would be utterly impossible without  
its aid."

## PLATINOTYPE.

---

Mr. S. G. KIMBER, of the Southampton Photographic Society, and Local Hon. Sec. of the Photographic Convention of the United Kingdom, 1906, writes as follows:—

“ You have indeed added another boon  
“to the pictorial Exhibitor by the pro-  
“duction of ‘ Japine ’ Platinotype, as he is  
“able to obtain permanent prints of the  
“most luscious quality, with beautiful  
“transparent shadows, in a most pleasing  
“colour, in a minimum of time, and with  
“the greatest ease and certainty.”

PLEASE MENTION THIS JOURNAL WHEN CORRESPONDING WITH ADVERTISERS.

ESTABLISHED 1894. ENLARGED 1895, 1896, 1905, AND JAN., 1907.  
EDITED BY H. SNOWDEN WARD.

*New Series. . . . Increased Size.*  
*Reduced Subscription Price. . .*  
*Many Improvements & New Features.*  
**Important Announcement.**

ON 1st January 1907 "THE PROCESS ENGRAVER'S MONTHLY" appears as an entirely separate magazine from "THE PHOTOGRAPHIC MONTHLY," with which it has been affiliated since its first issue in January 1894.

¶ 1. **The Reason.**—The growth of the photo-mechanical trade throughout the world, and the considerably increased support which "THE PROCESS MONTHLY" has recently received, seem to warrant an enlarged magazine, and one devoted entirely to photo-mechanical matters.

¶ 2. **The Increase in Size.**—In its new form the magazine will consist of at least twenty-four pages, crown 4to, adequately illustrated, with supplements (see ¶¶ 4, 5, 6), advertisements, and covers.

¶ 3. **The Reduction in Price.**—The retail price for single copies will remain as before (sixpence net; post free, eightpence; special numbers at higher rates), but the subscription price, including all supplements and special numbers, will be six shillings per annum, delivered free in the British Isles, or eight shillings, post free to the Colonies and foreign countries. Subscriptions may be through the trade; but the name, address, and trade status of the subscriber must be given, to secure advantages contemplated in ¶¶ 5 and 6.

¶ 4. **Pictorial Supplements** will be special features; and the Editor will endeavour to make "THE PROCESS MONTHLY" the recognized medium for introducing new and improved reproduction methods to those who use illustrations. This seems a most important part of the work of the enlarged magazine.

¶ 5. **"Confidential" Supplements.**—For years "THE PROCESS MONTHLY" has devoted space to commercial topics, price-cutting, etc., but has been hampered by the fact that it was purchasable by non-members of the trade, and therefore could not discuss figures freely. One great object of the attempt to convert all its regular readers into subscribers is that occasional "Confidential" supplements may be printed, which will be sent to *subscribers in the trade only*, and excluded from copies supplied to purchasers who are not known to be in the trade.

¶ 6. **Occasional "Special" Supplements.**—Subscribers are asked to specify the branch of the trade in which they are engaged, in order that special supplements may be sent occasionally to a particular section. For instance, when an important new dye for light-filters comes on the market, the maker may be prepared to give a small sample dyed film to each of the two or three hundreds who can use it, while he would not think of doing the same for the thousands of general readers; and to most of them the sample would be a mere curiosity, of no use.

¶ 7. **The arrangements for the January issue include**, in addition to much interesting technical and trade matter, three general supplements; (a) an exceedingly fine piece of work, reproduced, printed, and mounted by the Printing and Photographic Department of the Manchester Municipal School of Technology; (b) a colored half-tone, mounted print made by the newly perfected Aerograph Spray-printing machine, in illustration of an article on that machine and its working; and (c) a two-color design in illustration of an article by Chas. E. Dawson on a new and easy method of cutting flat-tint designs (for posters, etc.) and tints for working under half-tones.

A CONFIDENTIAL SUPPLEMENT dealing with actual costs of working in one of the largest block-making houses in the world will be sent only to proprietors and managers of half-tone concerns; and

A SPECIAL SUPPLEMENT, a film light-filter of the new Filter-yellow K, prepared by Wratten & Wainwright, Ltd., will be sent only to the first 300 subscribers who may be proprietors of half-tone houses, or men actually engaged in orthochromatic picture-copying.

24, Wellington Street, Strand, W.C.

## Divergent Opinion

OF THE

## B.J. Almanac, 1907

The PHOTOGRAPHIC JOURNAL  
(of the Royal Photographic Society).

"The ever-welcome 'B.J.' Almanac comes to hand this year in an infinitely more useful form than of yore by reason of the careful indexing which has been applied to its pages. The photographer, searching through its six hundred and odd pages for some item in which he is interested, will breathe a prayer for the welfare of the editor, whose labour has reduced the wearisomeness of the task. The contents of the book generally are of the character to which we have been accustomed, and nothing of interest which has occurred during the year appears to be absent from its pages."

The Editor of PHOTOGRAPHY.

"What should be the most useful portion of the book is the section given up to formulae, but the much desired editing has still to be done. At present it seems to be little more than a haphazard gathering arranged so as to give the greatest difficulty to anyone rash enough to seek for information from its pages."

The Standard.

"This work occupies a position of prime importance in the photographic world and is one of the few volumes that are daily consulted by an ever-increasing body of professional and amateur photographers and dealers. It was first published in 1859, and it has year by year increased in size, circulation, efficiency and influence, so that to-day it stands practically without a rival as a perfect manual of modern photographic practice. Its contents include an 'epitome of progress,' which is a classified review of the year's advances, formulae giving the latest photographic mediums."
